## EGYPTIAN MINISTRY OF CIVIL AVIATION

# FINAL REPORT <br> OF <br> THE ACCIDENT INVESTIGATION 

Flash Airlines flight 604
January 3, 2004
Boeing 737-300 SU-ZCF
Red Sea off Sharm El-Sheikh, Egypt

## Occurrence Summary:

On January 3, 2004, about 02:45:06 UTC, 04:45:06 Local time, Flash Airlines flight FSH604, a Boeing 737-300, Egyptian registration SU-ZCF, crashed into the Red Sea shortly after takeoff from Sharm el-Sheikh International Airport (SSH) in South Sinai, Egypt. The flight was a passenger charter flight to Charles de Gaulle Airport (CDG), France with a stopover in Cairo international Airport (CAI) for refueling. Flight 604 departed from Sharm el-Sheikh airport with 2 pilots (Captain and First Officer), 1 observer, 4 cabin crew, 6 off-duty crew members and 135 passengers on board. The airplane was destroyed due to impact forces with the Red Sea with no survivals.

The airplane had departed from Sharm el-Sheikh runway 22 R and was air born at 02:42:33 UTC, approximately $2^{1 ⁄ 2}$ minutes prior to the crash, and had been cleared for a climbing left turn intercept the 306 radial from the Sharm el-Sheikh VOR station located just north of runway 22R. This climbing turn allows departing flights to gain sufficient altitude before proceeding over higher terrain located along the flight path to Cairo. Flight 604 was operating in Egyptian airspace as a charter flight operating under the provisions of Egyptian Civil Aviation Regulations Part 121

## CONTENTS

1. FACTUAL INFORMATION
1.1 History of Flight
1.2 Injury to persons
1.3 Damage to Aircraft
1.4 Other Damage
1.5 Personnel Information

### 1.5.1 The captain

1.5.1.1 General
1.5.1.2 Background information
i- Beginning of his flying career.
ii- All airlines worked for prior to Flash Air
iii- History of military and civilian employment as pilot
iv- Retirement dates
v- NA
vi- "All" captain's training records (including his last recurrent training.
vii- Personal situation
1.5.1.3 (72-hour) history of the captain
1.5.1.4 Interviewing the individuals who trained and flew with the captain (including ground and simulator instructors)
1.5.1.5 Interviewing CAA inspectors who flew with captain.
1.5.1.6 Interviewing former head of operations at Flash Airlines
1.5.1.7 Additional factual documentation:(Captain)

- Number of days the captain had been working since his last day off.
- Captain interpersonal characteristics, including perceptions of fellow pilots regarding their capability for assertiveness.
- Familiarity of the two flight crew members with each other. (Including number of legs flown together this trip, number of legs flown together in the last 30 days.
- Description of how well the flying crew got along.
- Reported proficiency information. Outcome and comments from training records and proficiency check forms.
- Spatial disorientation or upset recovery training received at Flash Air or in the military.
- Captain's flying proficiency and cockpit style from fellow pilots, instructors, and/or check pilots.
- Flash Airlines chief pilot view regarding the departure procedure from SSH, based on company procedures.
- Number of departures from SSH previously made by the captain (day and night)
- The captain's time on Russian aircraft (MiG-21). (Dates and number of hours). ADI display configuration in comparison with B737-300 ADI display.
- The captain's time on American military transport aircrafts (C130). (Dates and number of hours). ADI display configuration in comparison with B737-300 ADI display.

### 1.5.2 The F/O

1.5.2.1 General
1.5.2.2 Background Information
i- Beginning of his flying career.
ii- All airlines worked for prior to Flash Air .
iii- "All" F/O training records at Flash (including his last recurrent training.
iv- Personal situation.
1.5.2.3 (72-hour) history of the F/O
1.5.2.4 Interviewing the individuals who trained and flew with the F/O (including ground and simulator instructors)
1.5.2.5 Interviewing CAA inspectors who flew with F/O.
1.5.2.6 Interviewing former head of operations at Flash Airlines
1.5.2.7 Additional factual documentation:(F/O)

- Number of days the F/O had been working since his last day off.
- F/O interpersonal characteristics, including perceptions of fellow pilots regarding their capability for assertiveness.
- Reported proficiency information. Outcome and comments from training records and proficiency check forms.
- $\quad$ Spatial disorientation or upset recovery training received at Flash Air
- F/O's flying proficiency and cockpit style from fellow pilots, instructors, and/or check pilots.

### 1.5.3 The Observer

General
Beginning of his flying career Interview with brother of observer pilot
CAA regulations regarding observation time
Flash Airline policy regarding observation time
1.5.4 Maintenance Engineer
1.6 Airplane Information
1.6.1 Airplane History
1.6.2 Cockpit Instrumentation1.6.2.1 Electronic Attitude Direction Indicator (EADI)1.6.2.2 Electronic Horizontal Situation Indicator (EHSI)
1.6.3 Lateral Flight Control System
1.6.4 Autoflight System
1.6.4.1 Autopilot System
1.6.4.2 DFCS ModeOperation of the FD vertical bar with "HeadingSelect" disengagement as the AP engages.
1.6.4.3 Flight Director
1.6.5 Engines
1.6.6 Airplane Maintenance
1.6.6.1 Maintenance Records
1.6.6.1.1 Maintenance Program Summary- Flash Airlines B737-300
1.6.6.1.2 Last Heavy Check
1.6.6.1.3 Repairs and Alterations
1.6.6.1.4 Aircraft Total Hours and Cycles
1.6.6.1.5 Weight and Balance Summary
1.6.6.1.6 Engines CFM56-3C-1
1.6.6.1.7 Engines Monitoring System
1.6.6.1.8 Flight Data Recorder/ Cockpit Voice Recorder
1.6.6.1.9 Aircraft Status
1.6.6.1.9.1 Minimum Equipment List (MEL)
1.6.6.1.9.2 Aircraft Condition Report(A/C Deferred Defects)
1.6.6.1.9.3 Type Certificate Data Sheet
1.6.6.1.9.4 Supplemental Type certificate1.6.6.1.9.5 Aircraft Directives (AD's)and Service Bulletins (SB)Summary
1.6.6.1.9.6 Prior Discrepancies/Accidents Involvement SU-ZCF
1.6.6.1.9.7 Logbook Forms
1.6.6.2 Contracted Repair Stations Listing
1.6.6.3 Maintenance Performance on the A/C before theAccident Flight1.6.6.4 The maintenance log sheets for the flights after12/31/031.6.6.5 The lack of write-ups on the TOGA problem andslat indication that existed on the entire 25 -hoursof FDR.
1.6.7 Weight and Balance
1.7 Meteorological Information
1.8 Aids to Navigation
1.8.1 Maps, charts, etc.
1.8.2 Sharm el-Sheikh Radar
1.8.3 Hurgada Radar
1.9 Communications
1.9.1 ATC communications/ Transcript
1.10 Aerodrome Information
1.11 Flight Recorders
1.11.1 Flight Data Recorder
1.11.2 Cockpit Voice Recorder
1.12 Wreckage and Impact Information
1.12.1 Scope of Sight and Wreckage group Field Note
1.12.2 Recovery Operation
1.12.3 Partial List of the Recovered Wreckage
1.12.4 Initial Observation
1.12.5 Wreckage Databases and Photos
1.13 Medical and Pathological Information
1.13.1. Egyptian Air Force - Medical Board Report
1.13.2. Medical factors related to "Spatial Disorientation" (SD)
A. FAA Advisory Circular regarding SD
B- MCA study regarding SD
C- Medical records for the captain related to any of theconditions conducive to SD.
1.13.3. Most recent medical certification.
1.13.4. General health information for each crew member
1.13.5. Toxicological testing.
1.13.6. Last civil medical check for captain
1.14 Fire

## 1. Factual Information

### 1.1. History of Flight

## Summary

On January 3, 2004, about 02:45:06 UTC, 04:45:06 Local time, Flash Airlines flight FSH604, a Boeing 737-300, Egyptian registration SU-ZCF, crashed into the Red Sea shortly after takeoff from Sharm el-Sheikh International Airport (SSH) in South Sinai, Egypt. The flight was a passenger charter flight to Charles de Gaulle Airport (CDG), France with a stopover in Cairo international Airport (CAI) for refueling. Flight 604 departed from Sharm el-Sheikh airport with 2 pilots (Captain and First Officer), 1 observer, 4 cabin crew, 6 off-duty crew members and 135 passengers on board. The airplane was destroyed due to impact forces with the Red Sea with no survivals.

The airplane had departed from Sharm el-Sheikh runway 22 R and was air born at 02:42:33 UTC, approximately $21 / 2$ minutes prior to the crash, and had been cleared for a climbing left turn intercept the 306 radial from the Sharm el-Sheikh VOR station located just north of runway 22R. This climbing turn allows departing flights to gain sufficient altitude before proceeding over higher terrain located along the flight path to Cairo. Flight 604 was operating in Egyptian airspace as a charter flight operating under the provisions of Egyptian Civil Aviation Regulations Part 121

## History of Flight

In the following history, comments originally in Arabic are translated in to English and appear in italics. A complete transcription of the CVR is contained in Exhibit C, CVR Group Factual Report

- Flash Airlines flight 604 Boeing 737-300 scheduling to depart Sharm El Sheikh at 0230 GMT 0430 local time.
- From Cockpit Voice Recorder information the first officer and observer were in the Cockpit at 02:14:30 the Captain was in the cockpit at 02:18:14.
- Load information and flight information were exchanged between the Flight Deck and Cabin Attendants.
- At 02:18:58 before start check list was requested by the Captain and was read by the F/O and responded by Captain and F/O completed at 02:20:17.
- The Cleared to Start checklist was carried out at 02:32:19, the After Start checklist at 02:35:36, and the Taxi checklist at 02:39:55.
- The ATC clearance was delivered at 02:38:15 and read back by F/O as follows:
- ATC Flash 604 destination Cairo as filed climb initially flight level 1401673 on the squawk.
- F/O Our clear to destination via flight plan route 140 initially 1673 on the squawk Flash 604 we have total pax135 God willing.
- $02 \mathrm{~h} 39 \mathrm{~min} 54 \mathrm{~s}, \mathrm{~A} / \mathrm{T}$ engaged (through the whole flight),
- The Take Off checklist was completed at 02:40:05.
- 02 h 40 min 38 s, F/O : "Flash 604 ready for departure",
- 02 h 40 min 46 s , TWR : "Flash 604 surface wind $280 / 13$ kts left turn to intercept radial 306 clear for take off 22R",
- $02 \mathrm{~h} 40 \mathrm{~min} 55 \mathrm{~s}, \mathrm{~F} / \mathrm{O}$ : "Clear for take off runway 22 R with left turn to establish 306 Sharm VOR, our Flash 604 clear for take off",
- 02 h 41 min 19 s, F/O : "Left turn to establish radial 306",
- 02 h 41 min 30 s, Captain : "Initially 140",
- 02 h 41 min 34 s, Captain : "Confirm initially 140",
- 02 h 41 min 35 s, F/O : "And Flash 604 confirm to the left to establish 306",
- 02 h 41 min 40 s , Captain : "Initial 140",
- 02 h 41 min 43 s, TWR : "Inch Allah",
- 02 h $41 \mathrm{~min} 44 \mathrm{~s}, \mathrm{~F} / \mathrm{O}$ : "And initially 140",
- Take off was initiated at 02:41:59 with standard call outs.
- At time 02:42:02 TOGA mode engaged and then disengaged at 02:42:04.
- Aileron movements during T/O roll and lift off were consistent with crosswind.
- 02 h 42 min 10 s, F/O : "Take off power set speed building up 80 kts throttle hold",
- 02 h 42 min 26 s to 02 h 42 min 33 s, Take off phase, Co-pilot : "V1 rotate, positive rate",
- 02 h 42 min 36 s, Captain : "Gears up",
- 02 h 42 min 38 s, gears are up (FDR), CAS 169,5 kts
- 02 h 42 min 43 s , Captain : "400 heading select",
- $02 \mathrm{~h} 42 \mathrm{~min} 44 \mathrm{~s}, \mathrm{~F} / \mathrm{O}$ : "400 heading select" (FDR heading select engaged),
- At time 02:42:48, Captain requested "Level Change"
- At time 02:42:49 the F/O announced "Level Change, MCP speed, N1 armed Sir".
- At time 02:42:59 the F/O announced "one thousand". At the same time, ATC reported the departure time and confirmed left turn clearance. The clearance was acknowledged by the F/O. This was the last ATC transmission from the flight crew. The aircraft rolled to $20^{\circ}$ left bank and began a climbing turn.
- 02 h 43 min 00 s, Captain : "N1 speed 210 flaps 1",
- 02 h 43 min 04 s , Captain : "Left turn",
- 02 h 43 min 05 s , TWR : "Flash 604 airborne time 44 when you ready to the left to intercept 306 radial report on course", (Aircraft at 1268 ft ),
- 02 h 43 min 11 s, Captain : "Left turn", ( 1528 ft , beft)
- $02 \mathrm{~h} 43 \mathrm{~min} 12 \mathrm{~s}, \mathrm{~F} / \mathrm{O}$ : "Roger when ready inch Allah",
- 02 h 43 min 18 s , F/O : "left turn to establish 306 Sharm VOR", (maximum recorded left roll is $21,8^{\circ}$ within that phase at 02:43:21),
- The turn continued as the magnetic heading approached $140^{\circ}$ (at an altitude of 3600 ft ), at which point the bank angle decreased to approximately $5^{\circ}$ left bank.
- At time 02:43:19, EgyptAir Flight (MSR 227), a flight from Hurgada inbound to Sharm el-Sheikh called ATC. Conversations between ATC and MSR 227 continue for approximately 60 seconds.
- 02 h 43 min 21 s, MCP selected speed recorded 219 kts ,
- 02 h 43 min 23 s, Captain: "Flaps up",
- 02 h 43 min 33 s , Selected heading recorded $106,8^{\circ}$,
- 02 h 43 min 35 s, Co-pilot : "Flaps up no light", ( $2196 \mathrm{ft}, \mathrm{CAS} 209 \mathrm{kts}$, Hdg 168, Pitch $10.9^{\circ}$, Roll $20,74^{\circ}$ left),
- At time 02:43:37, the Captain called for the After Takeoff checklist. There was not audible response from the F/O.
- 02 h 43 min 53 s , CAS 216,5 kts decreasing (reached a minimum value of 184.5 Kts at 2:44:23 and then started increasing),
- At time 02:43:55, the Captain called "Autopilot". There was no immediate response from any crew member. ( $3124 \mathrm{ft}, \mathrm{CAS} 216 \mathrm{kts}$, Hdg 142.7, Pitch $15.3^{\circ}$, Roll $7.7^{\circ}$ left)
- At time 02:43:58, the Captain stated "Not yet".(3320 ft, CAS 213.5 kts, Hdg $141.3^{\circ}$, Pitch $16.3^{\circ}$, Roll $6.6^{\circ}$ left)
- At time 02:43:59, the FDR recorded the autopilot was engaged, and that the roll mode transition to CWS-R mode. This transition would have resulted in loss of Heading Select Mode (3392 ft, CAS 212 kts, Hdg $140.6^{\circ}$, Pitch $17.5^{\circ}$, Roll $6.6^{\circ}$ left)
- At time 02:44:00, the F/O stated "Autopilot in command sir". (3468 ft, CAS 209.5 kts, Hdg $140.2^{\circ}$, Pitch $18.4^{\circ}$, Roll $6.6^{\circ}$ left)
- At time 02:44:01, the captain stated "EDEELO", (an Arabic exclamation expressing a sharp response of some kind). At the same time, the FDR records momentary aileron surfaces movements. The right aileron deflected to 7.2 degree TEU for one second
- At time 02:44:02, the CVR records the autopilot disconnect warning and the FDR recorded the autopilot disengaged. The aural warning lasted for 2.136 seconds. ( 3624 ft , CAS 207 kts , Hdg $139.9^{\circ}$, Pitch $19.3^{\circ}$, Roll $5.6^{\circ}$ left)
- During this time, an increase in pitch and decay in airspeed were observed
- At time 02:44:05, the Captain requested heading select. (3880 ft, CAS 203 kts, Hdg $139.5^{\circ}$, Pitch $20.5^{\circ}$, Roll $0.0^{\circ}$ left)
- At time 02:44:07, the F/O states "heading select" and the FDR records heading select mode engaging. This mode transition would have resulted in the reappearance of the flight director roll command bar. During this sequence, the aircraft' left-bank continued to decrease at a slow rate until the airplane was briefly wings level. ( 4056 ft, CAS $199 \mathrm{kts}, \mathrm{Hdg} 139.5^{\circ}$, Pitch $19.8^{\circ}$, Roll $0.35^{\circ}$ right)
- Beginning at this time, the FDR records a series of aileron motions that command a right bank and subsequent right turn.
- At time 02:44:18, the captain states "See what the aircraft did". At this point the aircraft bank angle was approximately $12^{\circ}$ to the right. ( 4824 ft , CAS 186.5 kts, Hdg $149.4^{\circ}$, Pitch $15.4^{\circ}$, Roll $12.6^{\circ}$ right)
- 02 h 44 min 23 s , CAS $184,5 \mathrm{kts}$ and will increase to the end of the flight,
- 02 h 44 min 25 s , last recorded speed selected 220 kts ,
- At time 02:44:27, the F/O states "Turning right, sir". Three seconds later, the captain responses "What". At the same time, bank angle is $17^{\circ}$ to the right and the FDR records the aileron motions to increase the right bank ( 5172 ft , CAS 186 kts, Hdg $160.6^{\circ}$, Pitch $13.3^{\circ}$, Roll $16.8^{\circ}$ right)
- At time 02:44:31, the F/O states "Aircraft is turning right". One second later, the captain response "Ah"
- At time 02:44:35, the Captain states "Turning right", at this point, the bank angle was $23.6^{\circ}$ to the right ( 5396 ft , CAS 192 kts , Hdg $174.7^{\circ}$, Pitch $11,7^{\circ}$ Roll $23,5^{\circ}$ right), last selected heading $84,9^{\circ}$ )
- At time 02:44:37, the Captain states - "how turning right" (5436 ft, CAS 195 kts, Hdg 179.6, Pitch $10.7^{\circ}$, Roll $27.7^{\circ}$ )
- At time 02:44:41, the Captain states "OK come out". ( $5468 \mathrm{ft}, \mathrm{CAS} 202.5 \mathrm{kts}$, Hdg $194.7^{\circ}$, Pitch $6.5^{\circ}$, Roll $41.8^{\circ}$ right) At this point, the bank angle was slightly more than $40^{\circ}$ right bank and the FDR records the ailerons returning to just beyond neutral, the high right roll rate stopped and a momentary left roll rate occurred resulting in a slight decrease in the right bank from $43.2^{\circ}$ at 2:44:40 to $41.8^{\circ}$ at 2:44:41 before additional aileron movements command an increase in the right bank.
- At time 02:44:41.5, the F/O states "Overbank. The bank angle at this time was just beyond $50^{\circ}$ right bank. The airplane reaches its maximum altitude of just over 5460 feet.
- At time 02:44:41.7, the Captain states "Autopilot". He repeats the statement at 02:44:43.4.
- At time 02:44:44, the F/O states "Autopilot in command". No autopilot engagement was recorded on the FDR. (5432 ft, CAS 209.5 kts, Hdg $210.5^{\circ}$, Pitch $3.5^{\circ}$, Roll $53.0^{\circ}$ right)
- At time 02:44:46, the Captain again states "Autopilot".
- At time 02:44:48, the F/O states "Overbank, Overbank, Overbank".(5276 ft, CAS 222 kts, Hdg $235.9^{\circ}$, Pitch $3.5^{\circ}$ nose down, Roll $68.9^{\circ}$ right).
- 02 h 44 min 51 s , Master caution recorded,
- At time 02:44:52.8, the F/O again states "Overbank". (At 02:44:53, 4628 ft , CAS 254 kts, Hdg $265^{\circ}$, Pitch $25.14^{\circ}$ nose down, Roll $91.4^{\circ}$ right)
- At time 02:44:53.4, the Captain responds "OK, come out".
- 02 h 44 min 54 s , aileron motion to the left during 9 s ( 4388 ft , CAS 264.5 kts , Hdg $270^{\circ}$, Pitch $29.7^{\circ}$ nose down, Roll $95.2^{\circ}$ right)
- At time 02:44:56, the F/O states "No autopilot commander".(3820 ft, CAS 289.5 kts, Hdg $277^{\circ}$, Pitch $37^{\circ}$ nose down, Roll $103.0^{\circ}$ right)
- At time 02:44:58, the captain states "Autopilot". At the same time, the FDR records a large aileron motion to the left and the airplane begins rolling back towards wings level. ( $3068 \mathrm{ft}, \mathrm{CAS} 317.5 \mathrm{kts}, \mathrm{Hdg} 281^{\circ}$, Pitch $43.2^{\circ}$ nose down, Roll $111^{\circ}$ right)
- At time 02:44:58.8, the observer states "Retard power, retard power, retard power"
- At time 02:45.01.5, the captain states "Retard power", and the FDR records both engine throttles being moved to idle.(Pitch $42.4^{\circ}$ nose down, Roll $39.2^{\circ}$ right)
- At time 02:45:02, the CVR records the sound of the overspeed warning.(1320 ft , CAS 382.5 kts , Hdg $306.9^{\circ}$, Pitch $40.6^{\circ}$ nose down, Roll $30.2^{\circ}$ right)
- Recovery from severe Right Bank and nose down pitch continued
- At time 02:45:04.3, the captain states "Come out". Bank angle was $15.6^{\circ}$ right, pitch attitude was $30.5^{\circ}$ nose down, altitude was 421 ft , and airspeed was 411.8 KIAS
- At time 02:45:05, the CVR records a sound similar to ground proximity warning ( 180 ft , CAS 416 kts , heading $315.7^{\circ}$, pitch $25.4^{\circ}$ nose down, right roll $19.3^{\circ}$ ),
- A/C impacted the water at about 02:45:06 with last recorded data:
- Bank Angle $19.3^{\circ}$ to the right
- Pitch Angle $25.4^{\circ}$ Nose down
- Vertical G. Load 3.96 (2.7)
- Speed 416 Kts

## Correlated FDR- CVR Data:

### 1.2. Injuries to Persons

There were no survivors.

| Injuries | Flight Crew | Cabin Crew | Passengers | Off-Duty Crew | Total |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Fatal | 3 | 4 | 135 | 6 | 148 |
| Serious | 0 | 0 | 0 | 0 | 0 |
| Minor | 0 | 0 | 0 | 0 | 0 |
| None | 0 | 0 | 0 | 0 | 0 |
| Total | 3 | 4 | 135 | 6 | 148 |

Table 1: Injury chart.

### 1.3. Damage to Airplane

The airplane was destroyed by impact with the water.

### 1.4. Other Damage

There was no other damage. Most of the wreckage remains on the floor of the Red Sea at a depth of approximately 1000 meters.

### 1.5. Personnel Information

Both the Captain and the First Officer were certified under Egyptian Civil Aviation Authority (ECAA).

### 1.5.1 The Captain

[^0]1.5.1.2. Background information.
i- Beginning of his flying career.
Refer to captain CV, and his training records item 1.5.1.2 (vi)
ii- $\quad$ All airlines worked for prior to Flash Air

- The captain joined the A.R.E. Military Aviation College on September 1968, and was graduated on May 1970
- He continued working as military pilot at A.R.E. Air Force since that date flying the L29, MIG17, MIG21, Buffalo (Dash 5), C130 types until he retired from the A.R.E. Air Force at the beginning of 2000
- He joined Scorpio Aviation working as a civil pilot on ATR 42 from March, 2000 up to December, 2001.
- He joined Flash Airline working as a civil pilot on B737-300 from February 2003 until 3 January 2004 (accident date)
(All his flying hours were flown as PIC)
iii- $\quad$ History of military and civilian employment as pilot The captain flew as a fighter pilot on L29, Mig17, Mig21 since his graduation until 1983. He then flew as a military transport pilot from that date on Buffalo and C 130 until his retirement from the Air Force at the beginning of 2000. (Refer to previous item)
iv- $\quad$ Retirement dates from A.R.E Air Force. Captain has retired from A.R.E. Air Force beginning of 2000
v- History of position flown for specific aircraft, and dates of upgrades (i.e., copilot to captain)
Refer to page 14 of the Factual Report
(All his flying hours were flown as PIC)
vi- "All" captain's training records (including his last recurrent training).

Letter issued by ECAA approving Flash Airline Basic Indoctrination Course for 4 trainees including Captain/ Khedr Abdallah Lasting 21 hrs from 24 May 2003 to 26 May 2003

The captain was married and had 3 children ages 29, 25 and 18 years. The eldest son is married and is doing post graduate studies in USA. The second son is an engineer. The youngest daughter is still studying in university.
The captain has no known problems of any kind. He is known to be devoted to his family. He did not suffer from any abnormal health or social problem.
(Refer also to page 72 of the Factual Report (Interviews regarding Captain Kheider Abdullah)
1.5.1.3. 72-hour history of the captain:

Refer to interviews on page 73 of the FR.
The captain and F/O left Cairo to SSH on January $1^{\text {st }}, 2004$ as passengers on Flash Airline flight departing Cairo at 15:00 GMT No more factual information could be obtained regarding the 72hour history.
1.5.1.4. Interviewing the individuals who trained and flew with the captain (including ground and simulator instructors)

# Interview with Captain/ Essam Eldin Brahmin Chief Pilot and instructor ATR 42 Scorpio Airlines during the period of employment of Captain/ Khedr in this Airline. 

- How well did you know Captain/ Khedr?

He was a colleague during work at the Egyptian Air force and when he joined Scorpio, we worked together as I was Chief Pilot. I was in charge of organizing his flying schedule and monitoring his standard through line checks.
He was a well disciplined pilot, observed his flying schedule without any problems, was always careful to observe duty time limitation and rest periods, had good relations with his colleagues, was cheerful with his crew and always prepared his flight carefully.
During line check he performed well. He was attentive to his work, communicated well with his crew and was not tense. His previous experience on military air transport made him comfortable in flying commercial air transport with relation to route experience and airway flying requirements.

- What routes were flown at this time?

Mainly domestic flights.

- Was Sharm El Sheikh one of your common destinations? Yes.
- What was the common departure procedure Followed out of Sharm EI Sheikh?
The standard procedure followed was depending on the runway in use a turn was initiated towards the sea while climbing in a wide pattern to cross the VOR 11000 Ft to proceed on the 306 Radial to Cairo.
- Did you as chief pilot and instructor see or have any report of any kind about Captain/ Khedr?
All comment and observations were good Captain and comfortable to work, always well prepared for his flight and kept his cockpit organized.
- Why did he leave Scorpio?

He left when the company stopped operations.

# Interview with Captain/ Emad Sallam Instructor Pilot on C130 In the Egyptian Air force <br> At the time Captain/ Khedr started to fly in the military air transport. 

## - How well did you know Captain/ Khedr?

As a pilot in the Air force we were colleagues although he was more senior than I, when he moved from the fighter squadrons to the air transport and when assigned to the C 130 I was an instructor and when he was assigned to training flights under my command was very willing and had no attitude about my being instructor with less seniority, he was always eager to learn and very attentive in the cockpit had no problem in asking for information from the crew with him and did not exercise unnecessary authority due to his rank, listened well to comments and observations of all the crew members without regard to rank and seniority was cheerful but well disciplined his training progress was standard.

## Interview with Captain/Essam Eldin Ibrahim Chief Pilot and instructor ATR 42 Scorpio Airlines during the period of employment of Captain/ Khedr in this airline.

## - How well did you know Captain/ Khedr?

He was a colleague during work at the Egyptian Air force and when he joined Scorpio we worked together as I was Chief Pilot I was in charge of organizing his flying schedule and monitoring his standard through line checks.
He was a well disciplined pilot observed his fighting schedule without any problems was always careful to observe duty time limitation and rest periods had good relations with his colleagues was cheerful with his crew and always prepared his flight carefully.
During line check he performed well was attentive to his work communicated well with his crew and was not tense his previous experience on military air transport made him comfortable in flying commercial air transport with relation to route experience and airway flying requirements.

- What routes were flown at this time?

Mainly domestic flights.

- Was Sharm El Sheikh one of your common destinations?

Yes.

- What was the common departure procedure Followed out of Sharm El Sheikh?
The standard procedure followed was depending on the runway in use a turn was initiated towards the sea while climbing in a wide pattern to cross the VOR 11000 Ft to proceed on the 306Radial to Cairo.
- Did you as chief pilot and instructor see or have any report of any kind about Captain/Khedr?
All comment and observations were good Captain and comfortable to work, always well prepared for his flight and kept his cockpit organized.
- Why did he leave Scorpio?

He left when the company stopped operations.
1.5.1.5. Interviewing CAA inspectors who flew with captain. Interviews to be carried out by OPS group
1.5.1.6. Interviewing former head of operations in Flash Airlines (No official former head of operation in Flash Airlines)
1.5.1.7. Additional factual documentation (Captain)

Number of days the captain had been working since his last day off.

Note:
The captain and F/O left Cairo to SSH on January $1^{\text {st }}, 2004$ as passengers on Flash Airline flight departing Cairo at 15:00 GMT

Captain interpersonal characteristics, including perceptions of fellow pilots regarding their capability for assertiveness.
All available information is available in pages 72-73 Factual Report
Familiarity of the two flight crew members with each other. (Including number of legs flown together this trip, number of legs flown together in the last 30 days.
According to the available information, the accident flight was the $3^{\text {rd }}$ sector in the last 24 hours.

Description of how well the flying crew got along. No information available

Reported proficiency information. Outcome and comments from training records and proficiency check forms.
Refer to 1.5.1.2 (vi)
Spatial disorientation or upset recovery training received at Flash Air or in the military. Al196
According to CAA regulations, Spatial Disorientation training is not mandatory
No available documents from Flash Airline concerning SD training. Some verbal reports from the Egyptian Air Force are available concerning the captain SD training the time he was serving in the Egyptian Air Force as a military fighter pilot. Inputs from different investigation partners are needed.
According to and CAA regulations, Upset Recovery training is not mandatory
Upset Recovery Training recommendation should be included in the Recommendations Chapter.

Captain's flying proficiency and cockpit style from fellow pilots, instructors, and/or check pilots.
Refer to 1.5.1.4 and 1.5.1.2 (vi)
Flash Airlines chief pilot view regarding the departure procedure from SSH, based on company procedures
According to Chief Captain Flash Airline and all other pilots questioned about departure procedure from SSH , all agree that a turn towards the sea is initiated with a bank angle depending on available rate of climb and captain's discretion to cross the VOR on course radial 306 at or above 10500 ft .

Number of departures from SSH previously made by the captain (day and night)

Within the last month, the captain has made five departures from SSH including the accident flight. (SAT 03-Jan-04 (night), FRI 02-Jan-04 (night), THU 25-Dec-03 (night), WED 24-Dec-03 (day) and TUE 23-Dec-03 (day))

The captain's time on Russian aircraft (MiG-21). Hercules transport aircrafts C130 (dates and number of hours). ADI display configuration in comparison with B737-300 ADI display.
Refer to captain CV, and item 1.5.1.2 (vi)
Captain flew approximately:
Russian Mig: 1000 flying hours (Russian ADI display)
C130: 5000 hours (Conventional ADI display)
ATR: 700 hours (Conventional ADI display)
Boeing 737: 700 hours (Conventional ADI display)

For B737-300 ADI refer to 1.16.1.9 (reference CairoMarch04Slides (March Progress Meeting - Cairo).pdf file)

Comparison with ADI Displays for other airplanes types might be made by the OPS group if needed

### 1.5.2 The First Officer

1.5.2.1. Summary: (Personal, training information)

Date of birth: January 1, 1979
Date of hire with Flash Airlines: May 22, 2002
Egyptian Commercial Pilot License Number 3284 (issued April 12, 1997)
TYPE RATINGS: CESSNA (ISSUED April, 12, 1997) I
B737-200 (ISSUED July, 22, 1998) II
B737-300/400/500 (ISSUED July, 18, 2002) II
Commercial Pilot License issued by the Federal Aviation Administration (FAA)
Certificate Number 2546582 (issued July 31, 1996)
Airplane Multi-Engine Land Instrument Airplane
Private Privileges
Airplane Single Engine Land
Limitations: None
Medical: First Class last check (May 5, 2003)
Limitations: None, valid till May 4, 2004
Initial Ground School Training:Written Test June 10, 2002
Oral Test May 22, 2002
Initial Simulator Training B-737-300/400/500: June 22-June 30, 2002
Initial Proficiency Check B-737-300/400/500: June 30, 2002
Line Check:
July 11, 2002
Last Proficiency Check:
May 15, 2003
Last Recurrent Training:
December 12, 2003

## FLIGHT TIMES:

| Total flight time $(\mathrm{hrs} / \mathrm{min})^{3}:$ | $788: 53$ |
| :--- | :---: |
| Total flight time B-737: | $242: 28$ |
| Total flying time last 24 hours $4:$ | $7: 15$ |
| Total flying time last 30 days: | $43: 45$ |
| Total flying Time 90 days: | $61: 10$ |

[^1]1.5.2.2. Background information.
i- Beginning of his flying career.

- The F/O began his ground training on the aircraft type 737-300 at Luxor Airway from 4 May 2002 to 16 May 2002
- The F/O completed the Full Flight Simulator Training and the Flight Training at Flash Airline on 30 June 02

Note:
Luxor Air training forms are approved training syllabus by ECAA. The audit of Flash Airline carried on January 2003 comment that Flash was still using training forms under the name of the previous operator who was also ECAA approved but they should change the forms to the name of Flash.
ii- All airlines worked for prior to Flash Air Refer to previous item
iii- "All" F/O training records at Flash (including his last recurrent training).
All flying hours before Flash were different training phases

ON FEBRUARY 15, 2001, ABOUT 1516 HOURS PST, A CESSNA 172N, N4922D, VEERED OFF THE RUNWAY AND COLLIDED WITH A TAXIWAY SIGN DURING LANDING ROLLOUT ON RUNWAY 28L AT THE MONTGOMERY FIELD, SAN DIEGO, CA. THE AIRPLANE WAS SUBSTANTIALLY DAMAGED. NEITHER THE AIRLINE TRANSPORT CERTIFICATED PILOT NOR PASSENGER WAS INJURED. PLUS ONE FLYERS, INC., IN SAN DIEGO, OPERATED THE AIRPLANE. VISUAL METEOROLOGICAL CONDITIONS PREVAILED AND AN INSTRUMENT FLIGHT RULES FLIGHT PLAN WAS FILED. THE PERSONAL FLIGHT WAS PERFORMED UNDER 14 CFR PART 91, AND IT ORIGINATED IN SCOTTSDALE, AZ. ABOUT 1135. AIRPORT PERSONNEL REPORTED THAT THE COLLISION OCCURRED ABOUT 1,000 FEET UPWIND OF THE RUNWAY'S THRESHOLD. THE AIRPLANE IMPACTED THE TAXIWAY "C" SIGN, AND VEERED OFF THE RUNWAY. THE AIRPLANE CAME TO A STOP ABOUT 200 FEET NORTH OF THE RUNWAY. THE PILOT STATED THAT DURING THE LANDING ROLLOUT, AS THE AIRPLANE WAS DECELERATING THROUGH ABOUT 50 KNOTS, THE LEFT WING SUDDENLY LIFTED UP. THEREAFTER HE LOST CONTROL OF THE AIRPLANE. HE ADDITIONALLY REPORTED THAT HE WAS UNAWARE OF THE REASON FOR THIS OCCURENCE. NO MECHANICAL MALFUNCTIONS WERE REPORTED WITH THE AIRPLANE.

ON FEBRUARY 15, 2001, ABOUT 1516 HOURS PACIFIC STANDARD TIME, A CESSNA 172N, N4922D, VEERED OFF THE RUNWAY AND COLLIDED WITH A TAXIWAY SIGN DURING LANDING ROLLOUT ON RUNWAY 28L AT THE MONTGOMERY FIELD, SAN DIEGO, CALIFORNIA. THE AIRPLANE WAS SUBSTANTIALLY DAMAGED. NEITHER THE AIRLINE TRANSPORT CERTIFICATED PILOT NOR PASSENGER WAS INJURED. PLUS ONE FLYERS, INC., SAN DIEGO, OPERATED THE AIRPLANE. VISUAL METEOROLOGICAL CONDITIONS PREVAILED, ANDAN INSTRUMENT FLIGHT RULES FLIGHT PLAN WAS FILED. THE PERSONAL FLIGHT WAS PERFORMED UNDER 14 CFR PART 91, AND ORIGINATED IN SCOTTSDALE, ARIZONA, ABOUT 1235 MOUNTAIN STANDARD TIME. AIRPORT PERSONNEL REPORTED THAT THE COLLISION OCCURRED ABOUT 1,000 FEET UPWIND OF THE RUNWAY'S THRESHOLD. THE AIRPLANE IMPACTED THE TAXIWAY "C" SIGN AND VEERED OFF THE RUNWAY. THE AIRPLANE CAME TO A STOP ABOUT 550 FEET FARTHER UPWIND OF THE SIGN AND ABOUT 200 FEET NORTH OF THE RUNWAY. THE PILOT STATED TO THE NATIONAL TRANSPORTATION SAFETY BOARD INVESTIGATOR THAT DURING THE LANDING ROLLOUT, AS THE AIRPLANE WAS DECELERATING THROUGH ABOUT 50 KNOTS, THE LEFT WING SUDDENLY LIFTED UP. THEREAFTER, HE LOST CONTROL OF THE AIRPLANE. HE ADDITIONALLY REPORTED THAT HE WAS UNAWARE OF THE REASON FOR THIS OCCURRENCE. NO MECHANICAL MALFUNCTIONS WERE REPORTED WITH THE AIRPLANE. IN THE PILOT'S PARTIALLY COMPLETED ACCIDENT REPORT, HE INDICATED THAT WHEN THE AIRPLANE WAS "ALMOST HALF WAY DOWN THE RUNWAY" THE LEFT WING ROSE UP, AND THEREAFTER HE LOST CONTROL OF THE AIRPLANE AS IT "VIOLENTLY" VEERED OFF THE RUNWAY. THE PILOT ALSO REPORTED THAT WHEN HE WAS ON FINAL APPROACH THE TOWER CONTROLLER REPORTED THAT THE WIND WAS FROM 270 DEGREES AT 6 KNOTS.

## NO RECORDS FOUND

## Interview with Brother of observer Pilot/ Ashraf Abdel Hamid:

Captain/Alaa El Saadany Training Captain with EgyptAir was interviewed by Dr. Adel Fouad and Captain Shaker Kelada who said that Ashraf Abdel Hamid was a lively person sociable and easy to get along with, was friendly confident and out spoken. Asked about his career as a pilot he said that he started his initial training in Cairo than went to Canada and obtained Canadian citizenship and Canadian pilot license and flew single engine planes. He then went to the USA and also obtained USA citizenship and flew there on single engine and Lear jets had a total of around 4000 hrs.

On a family visit to Egypt, he was persuaded by Captain\Sombaty (Operations Manager of Flash Airline), a colleague and personal friend to stay in Egypt and fly for Flash. He had attended B737 ground school course and was due for examination two days after the accident. He flew as an observer with Captain Sombaty who was assisting him to complete his B737 qualification.

## Correction:

The following statement included in page 15 of the factual report should be deleted: Airline training procedures require a certain amount of observation time prior to serving as an active crew member. The observer was assigned to this flight to observe as a part of that training requirement.

The following statement should replace it:
Ashraf Abdel Hamid was flying as an observer as it is common practice for operators in Egypt is to assign pilots joining an airline or upgrading to a new type to fly as an observer on the type to be flown to get acquainted with company routes and procedures of the operator and type

CAA regulations regarding observation time:
N/A
Flash Airline policy regarding observation time:
As required

### 1.5.4 Maintenance Engineer

Engineer Mostafa Erfan graduated from the National Civil Aviation Training Institute on September a6th 1972. He worked as a mechanic for the Kuwait Airways for twenty years during which he received the following training courses:

1- B 747-269B Mechanics Familiarization during the period from Feb $17^{\text {th }}$ 1979 to March $3^{\text {rd }}$ 1979. (Kuwait Airways).
2- Airbus Mechanics Familiarization Course during the period from October $6^{\text {th }}$ to October $18^{\text {th }} 1984$ (Kuwait Airways).
3- B767 Mechanics Familiarization A\& C Course during the period between February $7^{\text {th }}$ to February $19^{\text {th }}, 1987$ (Kuwait Airways).

In 1991 he attended the Cessna 188 course at DEVCO training center, and then he got his Egyptian license without type rating (LWTR) No 1525 on August $1^{\text {st }} 1992$ which is valid until July $27^{\text {th }}, 2004$.

He joined Flash Airlines two years ago; during these two years he had the following training and exams:

1- B737-300 type course at EgyptAir approved training center during the period from December $22^{\text {nd }}, 2002$ to February $27^{\text {th }}, 2003$.
2- Basic Indoctrination Course during the period from 13-14 June 2003.
3- An On Job Training for 9 months on Flash Airlines B737-300 fleet.
4- An approval authorization exam for the engine on November $2^{\text {nd }}, 2003$ and for the airframe November $3^{\text {rd }}, 2003$.

His approval No: 014 Valid until: July $26^{\text {th }}, 2004$
LWTR No: 1525 Valid until: July $27^{\text {th }}, 2004$

Issued on: Nov $28^{\text {th }}$, 2003
issued on: August $1^{\text {st }}, 1992$

### 1.6 Airplane Information

### 1.6.1 Airplane History

The accident airplane was a Boeing model 737-3Q8 airplane, serial number 26283, and was equipped with two CFM56-3 engines. The airplane was delivered on 22 October 1992 to an aircraft lessor. Since that time, it had been leased to several different operators and had carried US, UK, and Egyptian registration marks. The airplane had been operated by Flash Airlines since June 2001. At the time of the accident, the airplane carried Egyptian registration marks SU-ZCF and had accumulated 25603 flight hours and 17976 cycles.

| Aircraft Type | $:$ B737-3Q8 |
| :--- | :--- |
| Minimum Crew | $: 2$ (Pilot and Copilot) |
| Registration Marks | $:$ SU-ZCF |
| Serial Number | $: 26283$ |
| Manufacture Date | $:$ October 1992 |
| Line Number | $: 2383$ |
| Variable No | $:$ Total 148 Economy Class |

ECAA Minimum Number of Flight Attendant : 3

### 1.6.2 Cockpit Instrumentation

The airplane was equipped with an electronic flight instrument system (EFIS) which provides displays for most of the airplane's navigational systems. The major displays provided by the EFIS are: color displays of pitch and roll; navigational maps; weather; radio altitude and decision height; and autopilot and flight path information. The EFIS also provides displays of: airspeed; ADF/VOR bearings; ILS data; and stall warning information. There are two separate display screens for each pilot, the electronic attitude direction indicator (EADI) and the electronic horizontal situation indicator (EHSI). The EADI is mounted just above the EHSI in front of each pilot. In addition to the EADI and EHSI, each pilot's panel includes an airspeed indicator, a radio digital distance magnetic indicator (RDDMI) which displays directions and distance to radio navigation aids, an altimeter, a vertical speed indicator (VSI), and a clock. See Figure 1.6.2-1 for a simulated view of the captain's panel showing these instruments.

Figure 1.6.2-1 Example Captain's Instrument Display

### 1.6.2.1 Electronic Attitude Direction Indicator (EADI)

The Electronic Attitude Director Indicator (EADI) provides a multicolor display of airplane attitude, airspeed, flight director commands and various other data. The primary display is an artificial horizon which depicts the pitch and roll of the airplane. The artificial horizon line which separates the upper blue portion of the display from the lower brown portion moves up and down as the airplane pitches and tilts left and right as the airplane rolls. The display is designed such that the artificial horizon line that appears on the display is always parallel with the real horizon. Pitch and roll data for the captain's and first officer's EADI are supplied by separate left and right inertial reference units. In independent standby attitude indicator is installed on the captain's panel inboard of the EADI. In addition to attitude information, the EADI displays a moving airspeed scale along the left side and ground speed in the lower left corner. The upper portion of the EADI is called Flight Mode Annunciator (FMA). This area is used to display the current operating modes of the autoflight system to the crew. The FMA is separated into four separate areas in which are displayed (from left to right), the autothrottle mode, pitch mode, roll mode, and autopilot mode. See section 1.6.4 for further information about the autopilot and flight director.

An example EADI screen is shown in Figure 1.6.2.1-1.

Figure 1.6.2-2 Example EADI Display - In this example, the airplane is pitch is 7.5 degrees above the horizon and the roll angle is 20 degrees to the left, airspeed is 220 knots, ground speed is 238 knots, the autopilot mode is " N 1 ", the pitch mode is "MCP Speed", the roll mode is "heading select", and the autopilot mode is "Flight

Director"

### 1.6.2.2 Electronic Horizontal Situation Indicator (EHSI)

The EHSI provides horizontal navigation information to the flight crew. There are a number of display formats available which can be separately selected by the flight crew. On the accident flight, both the captain and first officer were using the expanded VOR display which is described below

Figure 1.6.2-3 Example EHSI Display - Expanded VOR Mode - Flag notes denote various options

### 1.6.3 Lateral Flight Control System

Lateral control is provided by an aileron and two flight spoilers on each wing which are controlled by either control wheel in the flight deck. A pair of cables transfers motion of the control wheels to motion of an aft quadrant located near the main landing gear wheel well.

Figure 1.6.3-1 Simplified Lateral Control System Schematic - Additional cable runs, jam protection features, and spoilers not shown

The aft quadrant is connected to the control valves of two independent hydraulic power control units. Either unit alone is capable of providing full-range lateral control. Artificial feel and wheel centering for lateral control is provided by the feel unit which consists of a centering cam, roller, and spring. Aileron trim is accomplished with aileron trim switches on the aft end of the pilots' control stand. The trim switches command an electro-mechanical linear actuator which repositions the feel and centering mechanism.
Two flight spoilers on each wing operate in conjunction with the ailerons through a spoiler mixer mechanism connected to the aft quadrant.
Two autopilot actuators are connected to the aft quadrant. Either or both of the autopilot actuators can move the aft quadrant, resulting in movement of both the control wheels and the ailerons. One feature of the lateral control system is that the position of the ailerons always corresponds to the position of the wheel. Even if aileron trim or the autopilots are in use, the relationship between the position of the control wheels and the position of the aileron is unchanged.

### 1.6.4 Autoflight System

The digital flight control system consists of a centrally located mode control panel (MCP), two independent flight control computers (FCCs), two aileron autopilot servo actuators, and two elevator autopilot servo actuators. Together, these components provide the functions of the autopilot and flight director. The MCP, located above the pilot's front panels and below the windows, provides a centralized location for all autopilot, flight director and autothrottle control selections. The FCCs receive flight crew requests and airplane sensor inputs which are used to generate flight director displays and, if the autopilot is engaged, command flight control surfaces.

### 1.6.4.1 Autopilot System

Each of the two FCCs provides an independent autopilot and are designated $A$ and $B$. Each FCC is connected to one aileron and one elevator servo actuator. The autopilot is engaged by selecting the appropriate push button on the MCP. If certain required conditions are met, the selected autopilot will synchronize the roll channel autopilot servo to the current position of the ailerons. Following synchronization, the autopilot servo will clamp onto the aft quadrant and begin moving the ailerons (and control wheel) in response to the flight path selected by the crew. A similar process occurs in the pitch channel.
During cruise, only a single autopilot is used. If the second autopilot is selected, the first autopilot is disengaged when the second autopilot engages. During approach, both autopilots may be used together for two channel operation.

Engage Switches:
The pushbuttons are normally-open, momentary contact switches which control an engage relay by means of electronic circuitry. Either channel can be engaged in CWS or CMD by pressing the appropriate switch. A light illuminates on the switch to indicate that the autopilot has been engaged, and each switch may be disengaged by pressing the switch again. Loss of power (28v) or ground to the relay will cause it to de-energize and the pushbutton switch light will go out. If CWS or CMD is pressed while either power or ground for the relay is not provided, the relay will not energize and the pushbutton light will not illuminate.

Autopilot Actuators: (Figure 1.6.3-1)
A- Four autopilot actuators are installed, two in the main wheel well area for the aileron axis and two in the aft fuselage for the elevator axis. One set, aileron and elevator, is controlled by the A autopilot system and the other set by the B autopilot system. The units are mechanically linked to aileron and elevator power control units (PCU's) which drive the flight control surface

B- A pressure switch is installed on each actuator. The switch closes when normal hydraulic pressure is applied to the PCU. The engage interlock voltage is wired through the switches.

C- Autopilot system electrical signals operate valves which modulate hydraulic pressure to displace a hydraulic piston and provide a rotary output to the respective PCU. Control and position signals are provided by the following components which re
installed on each actuator: engage solenoids, transfer valve, linear variable displacement transducer (LVDT), and pressure regulator.

## 1- Engage Solenoids

Two engage solenoids are on each autopilot module. Each solenoid is an electrically operated valve ( 28 volts dc) which, when energized, applies hydraulic pressure within the module. The ACTUATOR solenoid provides hydraulic pressure to the TRANSFER VALVE and to the DETENT SOLENOID. The detent solenoid provides hydraulic pressure to the detent mechanism. Both solenoids are energized at A/P engagement. However, the detent solenoid is delayed slightly from the ACTUATOR solenoid. The solenoids are attached to the module with four bolts. Electrical pins mate with wiring within the module when the units are installed. Hydraulic pressure is powered into the units through ports which align when the solenoids are installed.

2- Linear variable displacement transducer (LVDT)
The linear variable displacement transducer provides positional information for the actuator piston and provides an ac output signal in proportion to piston position.

## 3- Pressure regulator

The pressure regulator is in line with the hydraulic passages between the detent solenoid and the detent piston (which locks the actuator piston to the output crank). The regulator bypasses hydraulic fluid to limit the output force (autopilot authority) of the actuator when the unit is backdriven or stalled

## Autopilot Servo Schematic

Figure 1.6.4-1 Autopilot Actuator

### 1.6.4.2 DFCS Modes

Various pitch and roll modes are available and can be manually selected by the flight crew via the MCP. In some cases, automatic mode changes can occur in response to invalid sensor inputs, certain flight conditions, or selection of other compatible modes. During the accident flight, the following modes were used:

## Take-Off

Flight director guidance during takeoff is initiated by pressing the take-off/goaround (TOGA) switches located on the throttles. In addition to selecting flight director TOGA mode, these switches also signal the autothrottle to advance the throttles to takeoff power. In TOGA mode, the flight director provides pitch and roll guidance to the crew. If TOGA is engaged, no other modes may be selected until an altitude of 400 ft AGL.

## Level Change

Level Change is an autopilot and flight director pitch mode during climb or descent. In this mode, a fixed thrust level is selected and the autopilot will control the angle of climb or descent to hold the airplane's speed to the value selected in the speed window on the MCP. If the airplane is flying faster than the selected speed, the autopilot will command the airplane to pitch nose up to a steeper climb angle, thus lowering the speed. If the airplane's speed is slower that the selected speed, the autopilot will command the airplane to pitch nose down to a shallower climb angle, which will result in a speed increase. When Level Change mode is selected, "MCP SPD" appears in the pitch section of the flight mode annunciator (FMA) on the EADI. As the airplane nears the selected altitude, the autopilot will automatically transition to altitude acquire ("ALT ACQ" on the MCP) and then altitude hold ("ALT HOLD"). Level Change is available for both autopilot and flight director operation.

## Heading Select

Heading select is an autopilot and flight director roll mode used to turn to and hold a specific heading. The MCP contains a selected heading window, as well as a bank angle limit selector. The window displays the selected heading, a number from 0 to 359 , corresponding to the magnetic heading selected by the crew. The value can be changed by rotating the heading selector knob located immediately below the window. A bank angle limit selector is concentrically located on the same shaft. In Heading Select, the crew can select the bank angle of autopilot turns from $10^{\circ}$ to $30^{\circ}$ by $5^{\circ}$ increments. When heading select mode is engaged, the autopilot will command a turn towards the selected heading. The airplane will bank to the selected bank angle limit and will remain at that limit until the current heading begins to approach the selected heading. As the turn nears completion, the bank angle is reduced until the airplane is flying wings level on the selected heading. The direction of turn is determined to be the shortest turn between the current heading and the selected heading. If the airplane is already in a turn and the selected heading is changed to pass through the reciprocal bearing (greater than $180^{\circ}$ ), the direction of turn will reverse and the autopilot will seek the shortest turn to reach the selected heading. Heading select is active when "HDG SEL" appears in the roll section of the FMA and is available during both flight director and autopilot operation.

## Control Wheel Steering - Roll

Control wheel steering roll (CWS R) is a separate autopilot roll mode designed to reduce crew workload. CWS R mode may be manually selected via the CWS pushbutton on the MCP. In this case, flight director modes may be selected via the mode selection push buttons on the MCP. If certain conditions required for other
roll modes are not met or if a certain amount of force is applied to the control wheel, the autopilot mode will automatically change from CMD to CWS R.
In CWS R, the autopilot commands the aileron servo to follow the motions of the control wheel. If the pilot releases the control wheel, the autopilot provides aileron commands to hold the current bank angle and thereby continue the commanded turn. However, if the bank angle when the wheel is released exceeds $30^{\circ}$, the autopilot will command a roll back to a bank angle of $30^{\circ}$. If the bank angle when the wheel is released is less than $6^{\circ}$, the autopilot will command wings level and maintain the current heading. CWS R is active when "CWS R" appears in the autopilot section of the FMA. When the autopilot enters CWS R mode, the roll section of the FMA will be blank and the flight director roll command bar disappears. However, other roll flight director modes may subsequently be engaged.

MCP Speed
MCP speed is a pitch mode of the autopilot that is used when climbing or descending. In this mode, a fixed thrust level is selected and the autopilot will control the angle of climb or descent in order to hold the airplane's speed to the value selected in the speed window on the MCP. If the airplane is flying faster than the selected speed, the autopilot will command the airplane to pitch nose up to a steeper climb angle, thus lowering the speed. If the airplane's speed is slower that the selected speed, the autopilot will command the airplane to pitch nose down to a shallower climb angle, which will result in a speed increase. MCP speed mode is active when "MCP SPD" appears in the pitch section of the flight mode annunciator (FMA) on the EADI.

Operation of the FD vertical bar with "Heading Select" disengagement as the AP engages.

Refer to Boeing AMM 22-11-00 Page 38

### 1.6.4.3 Flight Director

The flight director is provided as an aid to the crew during manual flight and as a way for the crew to monitor the operation of the autopilot. The flight director consists of pitch and roll command bars which appears as horizontal and vertical magenta lines on the EADI respectively. When the airplane is following the flight path selected on the MCP, the flight director bars will be centered on the EADI display. If the airplane is flying below the selected path, the horizontal pitch bar will begin to rise on the display, indicating that a nose up command is required to regain the path. As the airplane regains the selected path, the command bar returns to the centered position. Similarly, if the airplane is following the selected roll path, then the vertical roll command bar will be centered. If the airplane deviates to the right of the selected path, the roll command bar will deviate to the left indicating that a bank to the left is required. It should be noted that the flight director roll command bar indicates the additional bank that is required to fly the selected path. For example, with the bank angle limit set to 20 degrees, if the airplane is in a 20 degree right bank as part of a 90 degree right turn, the flight director bar will be centered on the display because the airplane is on the desired path (in this case a 20 degree bank turn). As the turn continues and the airplane approaches the selected heading, the flight director bar will begin to move to the left indicating that the airplane should begin rolling left, out of the turn, and back towards wings level.

### 1.6.5 Engines:

General:
The airplane is powered by two CFM56-3C1 engines (Serial numbers are: "engine \#1" 857352 , "engine \#2" 856 481. The engine is a dual rotor axial flow turbofan. The N1 rotor consists of a fan, a three stage booster section connected by a through shaft to a four stage low pressure turbine. The N2 rotor consists of a high pressure compressor and a high pressure turbine. The N 1 and N 2 rotors are mechanically independent.

The main engine control (MEC) schedules fuel to provide the thrust called for by the forward lever setting. The fuel flow is further refined electronically by the power management control. Thrust is set by positioning the thrust levers. The thrust levers are positioned automatically by the autothrottle system or manually by the flight crew. The forward thrust levers control forward from forward idle to maximum. The reverse thrust control thrust from reverse idle to maximum reverse Engine indications are displayed on the center instrument panel by the Engine indication System (EIS). N1, EGT, N2, and FF/FU are the primary indications and are displayed as both digital readouts and round dial/ moving pointer indications. N1, EGT, N2 have operating and caution ranges and limits indicated by green and yellow bands and red dials. Oil Pressure and oil temperature indications are displayed with a round dial/moving pointer. Operating and caution ranges and limits are displayed with green and yellow bands and red dials. The oil quantity indicator displays a digital readout of quantity as a percentage of full

The low pressure spool (fan) rotating speed (N1) of the left engine (position 1) does not appear representative of the high pressure spool (core) rotating speed and fuel flow on the DFDR read out; however, the indicated core speed is working as well as the other parameters, which indicate most probably a data recording or read out problem for N1. (refer to Exhibit B FDR Group Factual Report)

### 1.6.6 Airplane Maintenance ${ }^{5}$

### 1.6.6.1 Maintenance Records

### 1.6.6.1.1 Maintenance Program Summary- Flash Airlines B737-300

Flash Airlines has developed their customized Maintenance Program. The Maintenance Program last revision was issued on January 20, 2003 and approved by the (ECASSA), Airworthiness Central Administration under approval No MOCA/FLASH/737-300/MP/R2/03. This Maintenance Program incorporated guidance from Boeing Maintenance Planning Document (MPD) Revision July 2002.

The Periodic Service Check is accomplished on layover. The check is performed as a walk-around, visual inspection and servicing when necessary.

The Routine Inspection is performed every 250 flight-hours (A Checks). A Routine Inspection Procedures Index is used to assure the check is completed. The Inspection consists of a visual inspection of the aircraft's major components, servicing, operational and functional checks.

### 1.6.6.1.2 Last Heavy Check

The last "A" check accomplished by Flash Airlines and the last "C" check and Structural inspection carried by Braathens Engineering and Maintenance for the SUZCF were as follows:
"8A" Check : December 12, 2003 at 25423:50 Flight Hours
"7C" Check : From Nov 3 - Dec 21, 2002 at 23531 Flight Hours
Last SI Check: From Nov 3 - Dec 21, 2002 at 23531 Flight Hours
Last 15 M Check: From Nov 3 - Dec 21, 2002
Last 45 M Check: From Nov 3 - Dec 21, 2002

### 1.6.6.1.3 Repairs and Alterations

[^3]
### 1.6.6.1.4 Aircraft Total Hours and Cycles

Total Hours at Time of Accident: 25603 Flight Hours<br>Total Cycles at Time of Accident: 17976 Flight Cycles

### 1.6.6.1.5 Weights and Balance Summary

According to the Egyptian Civil Aviation Regulations, ECAR 91 Appendix H attachment 1 the aircraft has to be reweighed every three years. Furthermore, aircraft must be reweighed if the effect of modifications on the mass and balance is not accurately known. Flash Airlines aircraft was weighed last time on December 19, 2002 in Braathens SAFE, Stavangar, Norway and recalculated by Flash Airlines after the reinforced cockpit door modification installation on November $1^{\text {st }}, 2003$, and the results were as follows.

| Empty Weight | $\vdots$ | 70794 lbs |
| :--- | :--- | :--- |
| Moment | $\vdots$ | $45921358.6 \mathrm{lb} . \mathrm{in}$ |
| \% AMC | $\vdots$ | $17.42 \%$ |

### 1.6.6.1.6 Engines: CFM56-3C-1

Engines are maintained in accordance with Flash Airlines Maintenance program and are based on the life cycle limits of the rotating components. CFMI Engine maintenance manual together with the applicable Service Bulletins and engine teardown data determine these limits. Overhauls are performed at the SNECMA MOROCCO Workshop or other authorized Certified Repair Station.

$$
\frac{\text { Engine Position } 1}{\text { (Left Side) }} \quad \frac{\text { Engine Position } 2}{\text { (Right Side) }}
$$

| Serial Number (ESN) | 857352 | 856481 |
| :--- | :--- | :--- |
| Time Since New (TSN) | 25314 hours | 26045 hours |
| Cycles Since New (CSN) | 17815 Cycles | 17523 Cycles |
|  |  |  |
| Date of Installation on SU-ZCF | August 1998 | Jan 3, 2003 |
| Time Since Last O/H | 8741 Hours | 1828 Hours |
| Cycles Since Last O/H | 6188 Cycles | 909 Cycles |

Engine Disks and First Limiters Status as per attached (refer to exhibit A, Maintenance Records Group Factual Report- attachment 02)

### 1.6.6.1.7 Engine Monitoring System

Flash Airlines engines are monitored as per the manufacturer (CFMI) engine condition monitoring program (Sage Trend Analysis program). Sage is a set of programs which collectively provide the functionality to perform standard condition monitoring of CFMI engines. Sage is designed to work in an interactive environment with the major analytical calculations performed at scheduled times throughout the day.
By reviewing the engine condition monitoring trend reports for both engines, they showed no deviation or important shift, the EGT margin is considerable ok. Engine

Condition Monitoring cruise trend sheet is attached (refer to exhibit A, Maintenance Records Group Factual Report- attachment 14)

| 1.6.6.1.8 Flight Description | Recorder/ Cock P/N | S/N | Test Date | Workshop |

### 1.6.6.1.9 Aircraft Status

### 1.6.6.1.9.1 Minimum Equipment List (MEL)

Flash Airlines Customized Minimum Equipment List CMEL was approved by the ECAA on Feb 23 ${ }^{\text {rd }}, 2002$

### 1.6.6.1.9.2 Aircraft Condition Report (A/C deferred defects)

No deferred items were recorded in the aircraft deferred snags log Book

### 1.6.6.1.9.3 Type Certificate Data Sheet

FAA "Type Certificate Data Sheet" number A16WE (revision 28, dated October 29, 1999) for B737-300 series airplanes was reviewed for compliance conditions and limitations. No discrepancies were noted. Type certificate Data Sheet attached (refer to exhibit A, Maintenance Records Group Factual Report- attachment 15)

### 1.6.6.1.9.4 Supplemental Type Certificates

Supplemental Type Certificates supplied by Flash Airlines were reviewed. One Supplemental Type Certificate was issued to install a Matsushita Audio Entertainment System in accordance with General Aerospace Engineering Order No GA-23-1042. STC attached (refer to exhibit A, Maintenance Records Group Factual Report- attachment 16)

### 1.6.6.1.9.5 Airworthiness Directives (AD) Summary and Service Bulletins (SB) Summary

The Airworthiness Directives compliance status list dated January $12^{\text {th }}, 2004$ (attachment 03) submitted by Flash Airlines was reviewed with special concentration on AD's carried out after the aircraft was leased by Flash Airlines.
The previous AD's Status which was forward to Flash Airlines during the aircraft delivery was reviewed with special attention to those AD's which had an open or repetitive status.
All listed Airworthiness Directives and Service Bulletins have been complied with no discrepancies noted.
Service Bulletins compliance status attached ((refer to exhibit A, Maintenance Records Group Factual Report- attachment 17)

### 1.6.6.1.9.6 Prior Discrepancies/Accidents Involving SU-ZCF

Per Flash Airlines records, no previous accidents were reported for the accident aircraft.

### 1.6.6.1.9.7 Logbook Forms

- The original aircraft Technical Log Book sheets were reviewed for the last three months from September 27, 2003 through December 2003 for discrepancies, no trends or discrepancies noted.
- Copy of the technical log book sheets listing as well as a list of technical log book entries and relevant corrective actions are attached to "Exhibit A Maintenance Records Group Factual Report"

### 1.6.6.2 Contracted Repair Station Listing

- EgyptAir Maintenance and Engineering
- Braathens Maintenance and Engineering
- Snecma Morocco Engine Services.

### 1.6.6.3 Maintenance Performed on the $A / C$ before the accident flight.

## A Maintenance done by Flash Airlines Tech Staff at Cairo Base

The Last Check carried out on the accident aircraft was an 8A check. The check was performed by Flash Airlines Technical staff at Cairo base station. The check work package included visual inspection, servicing, and operational checks. A routine borescope inspection for the HPT nozzles guides vanes and the combustion chamber was performed on both engines by EgyptAir with no findings. The work package was reviewed with no discrepancies.

## B Transient Check carried out for the Flight VCE/SSH

A transient check was carried out in VCE by engineer Motaz Awad on January $2^{\text {nd }}, 2004$ a copy of the interview with him is attached

## C Last PDC carried out for the Accident Flight

On 3 January 2004, aircraft SU-ZCF, a daily check was performed in accordance with the approved checklist as per the company maintenance schedule at SSH station just before the flight. The check was carried out by the accident flight on board engineer.

This was reported by incoming engineer

D Aircraft refueling before the Accident Flight and investigations done after the accident.

The Refueling was done for the accident aircraft on January $3^{\text {rd }}, 2004$ between 03:50 and 04:00 local time (UTC +2) for the quantity of 3500 Liters by truck
no 4432 belonging to Misr Petroleum Company (service invoice is attached) (refer to exhibit A, Maintenance Records Group Factual Report- attachment10)

The same truck had refueled the following airplanes on the same date:

- EgyptAir aircraft A320 SU-GBF at 02:05 LT before the accident aircraft.
- Taroum aircraft YR-GGX at 04:20 LT after the accident aircraft.
- EgyptAir aircraft SU-GCD at 05:10 LT after the accident aircraft.

After the aircraft accident, three fuel samples had been drawn from the Misr Petroleum fuel truck on January $3^{\text {rd }}, 2004$ at 12:45 local time. One of them was used for a dehydrated Copper Sulfate capsule field inspection for fuel water content, which was satisfactory (attachment 11). The two others samples were sent to the following laboratories for analysis:

- The Egyptian Petroleum Research Institute Nasr City, Cairo (refer to exhibit A, Maintenance Records Group Factual Reportattachment 12)
- Misr Petroleum Company, Ghamra Research Center Laboratory (refer to exhibit A, Maintenance Records Group Factual Report- attachment 13)

The Egyptian Petroleum Research Institute (EPRI) performed the Jet (A-1) fuel analysis, ASTM distillation and ASTM D-86. The results of these analyses show that all the values are within limits except for the water content, ppm, which is 48 , and the max is 30 .

The Misr Petroleum Co, Ghamra Research Center Laboratory performed the same analyses done by (EPRI), all the results comply with the requirements of DESSTAN 91-91 issue 4 (DERD 2494) and the joint fueling systems "Checklist" specifications for JET A-1 issue 19 Sept, 2002.

### 1.6.6.4. The maintenance log sheets for the flights after 12/31/03

Lost on board and no copies prior to departures from SHH which is a violation of ECAA regulations. Necessary measures are taken by ECAA to ensure adherence.
1.6.6.5. The lack of write-ups on the TOGA problem and slat indication that existed on the entire 25 -hours of FDR.
Status of the technical log is not known due to being lost on board.

### 1.6.7 Weight and Balance: 6

The Flash Airlines weight and balance calculations provided to the flight crew contained the following information ${ }^{7}$ :

[^4]|  | Weight (kilograms) |  |
| :--- | :--- | :--- |
| Total Traffic Load | $11,450^{8}$ |  |
| Dry Operating Mass | 33,200 |  |
| Actual Zero Fuel Mass | 44,650 |  |
| Maximum Zero Fuel Mass | 47,627 |  |
| Takeoff Fuel | 7,000 |  |
| Actual Takeoff Mass | 51,650 |  |
| Maximum Takeoff Mass (Certificate Limit) | 63,276 |  |
| Landing Mass | 49,650 |  |
| Maximum Landing Mass (Certificate Limit) | 51,709 |  |

| Zero Fuel Mass Center of Gravity (CG) | $20.0 \%$ |  |
| :--- | :--- | :--- |
| Zero Fuel Mass CG Limits 9 | $8.0 \%$ Forward | $28.4 \%$ Aft |
| Takeoff Mass CG | $18.0 \%$ |  |
| Takeoff Mass CG Limits ${ }^{9} 10$ | $6.7 \%$ Forward | $27.9 \%$ Aft |

Stabilizer Trim settings for takeoff were:

| Flaps 1 or 5 | $43 / 4$ Units |
| :--- | :--- |
| Flaps 15 | $33 / 4$ Units |

According to the Flash Airlines Flight Operations Manual Chapter 6, Paragraph
6.1.8.3, Passenger and Baggage Masses, the following chart was published:

|  | Male | Female |
| :---: | :---: | :---: |
| All flights except | 88 kg | 70 kg |
| Holiday | 83 kg | 69 kg |
| Children | 35 kg | 35 kg |

${ }^{8}$ A review of the Load and Trim Sheet indicated a low 100-kilogram error. The total cargo weight plus passenger mass (Total Traffic Load) should be 11,550 kilograms. Correspondingly, the Zero Fuel Mass, Takeoff Mass, and Landing Mass will be low in error by the same 100-kilogram Mass.
${ }^{9}$ Estimated Zero Fuel Mass CG limits were derived from Flash Airlines Load and Trim sheet index chart based upon a Zero Fuel Mass of 44,650 kilograms.
${ }^{10}$ Estimated Takeoff Mass CG limits were derived from Flash Airlines Load and Trim sheet index chart based upon a Takeoff Mass of 51,650 kilograms.

A review of the accident Load and Trim Sheet indicated a Passenger Mass of $9,450 \mathrm{~kg}$. If 350 kg is removed for 10 children ( $10 \times 35 \mathrm{~kg}$ ) the result is $9,100 \mathrm{~kg}$. Dividing the 125 adult passengers into the $9,100 \mathrm{~kg}$ would give an average value of 72.8 kg per adult passenger.

Using the table above, and assuming $50 \%$ Male and $50 \%$ Female adult passengers, the worst-case difference in weight calculation would be the following:

The average weight of male and female for all flights except would be $88 \mathrm{~kg}+70 \mathrm{~kg} / 2=$ 79 kg per adult passenger.
$79 \mathrm{~kg} \times 125$ passengers $=9,875 \mathrm{~kg}$
The represents an increase in weight of 775 kg .
Using this value for Load and Trim calculations provided the following information:

| Takeoff CG | $18.2 \%$ MAC |
| :--- | :--- |
| Zero Fuel Mass CG | $20 \%$ MAC |
| Takeoff Trim (flaps 5) | $43 / 4$ Units |

These worst-case differences in values for passenger weight still fall within structural and calculated limitations for the airplane.

Fig 1.6.5-1 Copy of the Accident Flight Load Sheet

### 1.7 Meteorological Information: 11

Sharm El Sheikh does not provide Automatic Terminal Information Service (ATIS).

The SSH weather at $0200 Z$ was reported as:
270 degrees at 06 knots, ceiling and visibility OK (CAVOK) ${ }^{12}$, temperature 17 degrees Celsius, dew point minus 6 degree Celsius, altimeter 1011 HectoPascals (hPa), No significant change (NOSIG) ${ }^{13}$.

The SSH weather at $0300 Z$ was reported as:
280 degrees at 08 knots, ceiling and visibility OK (CAVOK) temperature 17 degrees Celsius, dew point minus 6 degree Celsius, altimeter 1011 HectoPascals (hPa), No significant change (NOSIG).

[^5]${ }^{13}$ NOSIG, this terminology means no significant change expected

2:58:15 C>P
    P>C
    P>C Sharm MSR227
    C>P
                            Go Ahead Sir
P>C We heard on frequency 121.5 some one from Flash
        speaking, I do not know if it is 604 or it is another Flash
                                    Aircraft
C>P It is 604, there is no other aircrafts
P>C He was speaking on 121.5, so it is O.K.
C>P Thank you very much Sir
P>C
C>P
P>C
C>P
```

N.B. Frequency 121.5 was checked no transmission was recorded at the time of the accident with any traffic

### 1.10. Aerodrome Information

According to the Aeronautical Information Publication (AIP), Sharm el-Sheikh International Airport is located 23 kilometers northeast of the city. The elevation of the airport is 143 feet mean sea level. The airport had two paved parallel runways; $04 \mathrm{~L}-22 \mathrm{R}$ and 04R-22L. Both runways were 3081 meters in length and 45 meters in width. Runways 04R and 04L have CAT 1 Approach Lighting System and runways 22R and 22L had Simple Approach Lighting System. Neither runway had runway centerline lights.

According to the AIP Flight procedures, there were no standard departures and standard arrival routes or any other systematic procedures established within Sharm el-Sheikh approach airspace, heading, flight level, speed and or holding instructions shall be specified in approach control clearances to arriving and departing flights as appropriate to meet the requirements of traffic conditions.
Air Traffic Control Services for Sharm el-Sheikh
An Interview with the Director of Radar Airports, National Air Navigation Service Company indicated that at SSH, the local controller and the departure controller were the same person. The previous last flight departure before the accident flight departed about one hour earlier. An arrival flight landed less than 10 minutes after the accident flight departed. Radar was operating but no radar service was provided to the accident flight.

According to the Director, there were no Standard Instrument Departures (SIDs), or Standard Terminal Arrival Routes (STARs) in Egypt. Clearance was provided to the accident flight crew while on the ground and the departure included a left turn at pilot's discretion and to climb to Flight Level (FL) 140 and to intercept the 306 VOR radial. MEA for this sector is 10500 ft .

According to the Director, the prevailing winds at SSH require the use of runway $04 \mathrm{~L} 70 \%-80 \%$ of the year. On the date of the accident, runway 04 L was being used. However, sometime during the day prior to the accident, the runway was changed to 22R.

There was no inspection of the runway after notification of the accident, however, it was stated that the landing airplane after the accident did not report debris on the runway. There is a daily runway inspection performed at SSH.

For AIP information, see attachment

### 1.11. Flight Recorders

1.11.1. Flight Data Recorder ${ }^{15}$

The accident airplane's flight data recorder (SSFDR), part number 980-4120-DXUN S/N 10069, was retrieved from the Red Sea on January16, 2004 by the French Navy. The FDR was immersed in water and sealed in an ice chest and transported to MCA, accident investigation laboratory at Cairo.

- Readout of the FDR was accomplished using the laboratory's playback hardware, Hand held Down Load unit manufactured by ALLIED SIGNAL Part No. 964-0446-001 and recovery/ analysis/ presentation system (RAPS) software.
- In spite of the damage that had occurred to the external case of SSFDR, the internal solid state memory was in good condition and all the available data was retrieved. RAPS considered the recorded signal and data quality to be very good.
- Data plots and tabular listings of each data parameter for the entire accident flight are included in this report as Appendix "exhibit B, FDR Group Factual Report". The entire 25-hour contents of the FDR were also transcribed,

After the cockpit voice recorder (CVR) timing had been compared to the SSFDR vhf microphone keying and Autopilot disengages warning, a time correlation was developed. (refer to exhibit B, FDR Group Factual Report)

[^7]
### 1.11.2 Cockpit Voice Recorder ${ }^{16}$

- The accident airplane's Cockpit Voice data recorder (CVR), Fairchild, Part no. 93-A100-80, serial no. 57994 was retrieved from the Red Sea on January17, 2004 by the French Navy. The CVR was immersed in water and sealed in an ice chest and transported to MOCA, accident investigation laboratory at Cairo.
- Readout of the CVR was accomplished using the laboratory's playback hardware and software as follow:

## Download Unit:

A100 CVR play back Deck - Store 4DS
Audio Analysis System:
MPL 1024, 12 Channel Microphone Mixer - Samson
Filter : PCAP II (Samson)
Amplifier: Samson - Servo-550 Studio Amplifier

## Software:

Vegas 4 - Sound Forge 6 -PCAP II

- The recorder consisted of four channels of audio information.

Channel One:
Channel Two:
Channel Three:
Channel Four:

First officer hot mic.
Area Mic.
Observer hot Mic.
Captain hot Mic..

- After the initial retrieved sound task was completed another effort was undertaken with the assistance of BEA expert as follows:
o The output signal from the tape deck playback machine was too low compared to the recording on the same conditions in BEA. This problem was solved by increasing the output level when the screw of the adjustable gain control was turned clockwise.
o The sensitivity of the acquisition audio card of the PC was not good enough to capture correctly the audio signal coming from the tape deck player. This problem was solved by changing the value of the "Variable Signal Levels" on the hardware setting of the audio card, from the manufacture value +4 to -10 . The gain was increased and the input signal amplified.
o The speed of the tape was not correct with an interference of the power ( $115 \mathrm{~V}, 400 \mathrm{~Hz}$ ) measured at 375 Hz . It was not possible to adjust properly the speed of the tape with the device installed. This problem is solved by resembling the wave file with a correct ratio $(400 / 375=1.0665)$.

[^8]o Some high frequencies were missing when doing the spectrum analysis. This problem was solved by using a sampling rate of 32000 kHz instead of 22000 kHz .
o The alignment of the head installed on tape deck player was checked, adjusted and was found satisfactory prior to playback the tape.

A new copy of the CVR was performed. This recorded copy is satisfactory.

### 1.12. Wreckage and Impact Information: ${ }^{17}$

### 1.12.1 Scope of Site and Wreckage Group Field Notes

The scope of this report is the recovery operations that took place from 3 January 2004 through 5 February 2004 in the Red Sea off Sharm elSheikh, Egypt and initial inspection for the recovered parts. Recovery operations initially consisted of the recovery of floating wreckage elements only. Recovery of the underwater wreckage (including FDR and CVR) began when the first ship equipped with a suitable Remote Operated Vehicle (ROV), arrived at the accident scene on 11 January 2004.
This report provides a summary of the recovery operations and documents the wreckage that was identified and recovered.

### 1.12.2 Recovery Operations

## Survival aspects

The initial search for possible survivors and the recovery of bodies were priorities for the rescue and investigation teams. Rescue teams were on site minutes after the accident. They searched for survivors but due to the high energy impact of the aircraft with the sea surface, the depth of the water in this area, their efforts were unsuccessful in recovering any survivors.

Efforts were made to locate human remains by use of deep sea cameras and robots but were also not successful due to the location of the wreckage and the depth of more than 1000 meters.

## Floating Wreckage

Figure 1.12.4-1 Water depth map

[^9]The floating wreckage which was recovered shortly after the crash was stored in a hangar in Sharm el-Sheikh airport. On 11 January 2004, the Site and Recovery Group met in the hangar for wreckage inspection. The wreckage was then identified (as much as possible), inspected, segregated (aircraft parts or personal effects). Later, the personal effects were transferred to the Egyptian Legal Authority in Sharm el-Sheikh. A database for the floating wreckage was created (including wreckage pictures).

## Underwater Wreckage

Because of the depth of the Red Sea in the area where the accident occurred (approximately 1000 meters), specialized recovery resources were required for the submerged wreckage. The French vessels "lle de Batz" and "Janus II" were contracted to conduct the underwater wreckage survey and recovery. Both vessels were equipped with deep water recovery capabilities consisting of submersible Remotely Operated Vehicles (ROV). The necessary support equipment to accurately locate and map the airplane wreckage was provided by the French Navy. An oceanographic vessel, the "BeautempsBeaupré" was sent to the accident site to undertake a bathymetry (depth mapping) of the seabed and a survey of tidal currents.

Figure 1.12.4-2 ROV

## FDR / CVR Recovery

The initial focus of the underwater recovery operation was finding and retrieving the protected recorders, the Cockpit Voice Recorder (CVR) and Flight Data Recorder (FDR) and mapping the searched areas. Each recorder is equipped with an acoustic transmitter, called a "pinger" that transmits a detection signal that can be used to locate the box. Based on the initial determination of pinger locations, the ROV from Ile de- Batz, Scorpio, began a visual search using its cameras to find the recorders. To refine the location of the pingers, a network of sonobuoys (GIB, GPS Intelligent Buoys), (see Appendix 5 for detailed description of this operation), was employed in a cooperative effort between the French and Egyptian Navies. This method produced a new pinger position accurate to within 10 meters and the ROV was moved to the new location. A visual search of a grid created around the new pinger location resulted in discovery of the FDR on 16 January 2004.

The FDR was recovered by the ROV and taken onboard the lle de Batz. Custody of the recorder was transferred to the Investigator in Charge, at the port of Sharm El Sheikh.

The pinger of the second recorder (CVR) was initially identified approximately 800 meters north of the first pinger. However, it was decided to continue the visual search using grids in the area where the first recorder was found. This search was successful and resulted in finding of the CVR on 17 January 2004 (approximately 24 hours after the FDR). It was also taken onboard the lle de Batz and custody was transferred to the Investigator in Charge at the port of Sharm El Sheikh.

FDR underwater Location: N27 52.3605, E34 22.0165.
CVR underwater Location: N27 52.3467, E34 22.0207.

The recorders were both sent to Cairo for read out and analysis.
The focus of the recovery operation then changed to detailed mapping of the wreckage and recovery of selected airplane equipment. In addition, the recovery operation included recovery of any equipment deemed important to the investigation based on the review of the FDR and CVR in Cairo.

## Wreckage Mapping

During the structured search for the recorders, the position (latitude and longitude) and description of surveyed wreckage was recorded. Following recovery of the FDR and CVR, additional grids were defined for ROV operations. These grids were used to systematically survey and document the entire wreckage area. The positions of large pieces, such as the three landing gears and the cores of the two engines were identified.

Data from both ships involved in mapping and recovery were consolidated into a single listing of all surveyed wreckage, which is included herein as Appendix 2.

The distribution of wreckage is included within a rectangle of approximately 275 by 440 meters defined by the following corner point coordinates:

North corner: $\quad N 27^{\circ} 52,559$ E $34^{\circ} 21,933$
East corner: $\quad N 27^{\circ} 52,410$ E $34^{\circ} 22,126$
South corner: N 27 ${ }^{\circ} 52,294$ E $34^{\circ} 22,022$
West corner: $\quad N 27^{\circ} 52,450$ E $34^{\circ} 21,817$
Multiple surveys of the area confirmed the containment of the wreckage within these established boundaries.

## Recovered Wreckage

The investigation team developed a strategy for wreckage recovery based on the review of the FDR and CVR undertaken in Cairo. Flight control actuation components and flight deck systems were considered as a priority.

A system was developed for recording the description, external dimensions and the location, in latitude and longitude coordinates, of all recovered wreckage pieces. A database of recovered floating wreckage is included herein as Appendix 3. Another database documenting all wreckage recovered by Ile de Batz and Janus II is included as Appendix 4. Both databases reference digital images of all floating and recovered wreckage.

Recovered wreckage was stored aboard the ships in sea water until taken ashore and loaded onto trucks. All of the recovered wreckage is stored in a hangar at Sharm El Sheikh Airport and is under the control of the investigative authorities.

### 1.12.3 Partial list of the Recovered Wreckage

- Parts of the horizontal stabilizer central section structure (called "Texas Star"), elements of the elevator structure and components of the elevator control system, including both elevator PCU's (Power Control Unit), both autopilot actuators, the feel and centering unit including the feel actuator.
- Horizontal stabilizer jackscrew and actuator gearbox.
- Vertical stabilizer structure with rudder control system components, including the main rudder PCU and standby rudder PCU, the feel and centering mechanism and with the trim actuator.
- Aileron PCU, spoiler mixer and TBD spoiler actuators.

### 1.12.4 Initial Observations

- The two engines were found approximately 24 meters apart
- The left and right main landing gear assemblies were found in between the two engines
- The recovered thrust reverser actuator was found retracted
- The recovered leading edge flap actuator was found retracted
- The recovered trailing edge flap jackscrew indicates that flaps were retracted
- The stabilizer jackscrew was measured at 7.5 inches between the flat of the ball nut and the flat of the end stop which corresponds to a stabilizer leading edge position between 2 and 3 degrees down or a trim unit setting between 5 and 6 pilot units. 18

[^10]
### 1.12.5 Wreckage Data bases and Photos

The full data base and photos of the wreckage are on a CD, which is which is available at the Egyptian Civil Aviation Ministry (MCA). This CD contains:
a. A folder with three Excel files for wreckage complete data base.
i. Floating Wreckage data base.
ii. Recovered Wreckage data base.
iii. Underwater Surveyed Wreckage data base.
b. A folder for photos with four sub-folders
i. Floating Wreckage Photos: 104 photos.
ii. Recovered Wreckage Photos: 98 photos.
iii. Underwater Surveyed Wreckage Photos: 330 photos.
iv. Wreckage Recovery Process Photos: 25 photos

### 1.13. Medical and Pathological Information

### 1.13.1. Egyptian Air Force - Medical Board Report

From : Egyptian Air Force - Medical Board
To : Chairman of Civil Aviation Medical Board
Subject: Medical records of RET. AVM Kheider Abdullah Saad

## 1. Sequence of medical records

a) Medically fit for all flying duties as from his first medical examination dated 30/05/1970.
b) Amend to be medically fit for all flying duties to be reexamined every sis months as of 14/07/1982.
c) Amend to be medically fit for all flying duties (remove six months restriction) as of 22/04/1985.
d) Medically fit for all flying duties until his last medical examination dated 08/01/1997.
2. Medical History ${ }^{19}$
a) Admitted to hospital on 06/02/1988, diagnosed (cut wound on left hand) sick leave until 20/02/1988, return to normal duty.
b) Admitted to hospital on 26/04/1999, released on the same day, diagnosed (effusion left knee).
c) Examined on 03/11/1999, fit for all flying duties as per last medical exam.

## During Service A.F. Pilots are subjected to the following:

a) Tests for Spatial Disorientation as part of his routine periodic physical examination.
b) Sessions of physiologic training which include:

- Sudden Decompression.
- Certificate.
- Spatial Disorientation Training Chair.

No report was found of any medical factors related to Spatial Disorientation.

[^11]

### 1.15. Survival Aspects

Refer to 1.12 Wreckage and Impact Information
1.16.1. Tests and researches conducted by Boeing and Honeywell:

General:
A. The FDR records the movements of the pilot's controls (e.g. control column, control wheel position and rudder pedals), the movement of the control surfaces (e.g. elevator, aileron and rudder) as well as motion of the airplane (e.g. pitch and roll attitude and heading angle). The performance evaluation was conducted to determine if the control surfaces were responding normally to the pilot's controls and if the airplane was responding normally to movement of the control surfaces.

In order to accomplish this work, Boeing's 737-300 aerodynamic simulation model was used to recreate the accident flight. The simulation calculates the response of the airplane to movement of the flight control surfaces - for example, it can calculate the roll rate resulting from a 10 degree deflection of the ailerons. The simulation has been verified by comparison against actual flight test data and was used for the design and certification of the 737-300 airplane. In addition, the simulation is the basis for 737-300 crew training simulators used around the world. It should be noted that the 737-300 simulation model is essentially a computer program that represents a nominal airplane with nominal engines. Small differences between the simulation and individual airplane's behavior are common and expected due to differences in control surface rigging, engine wear, and other normal tolerances.

## B. Performance Evaluation

FDR data are recorded at relatively low sample rates and are recorded from different sources, some of which have inherent biases. Because of these issues, a kinematic consistency (KINCON) process was used to supplement the FDR data and calculate additional parameters to be used in the performance analysis. Kinematic consistency analysis is a general practice for processing flight data (either flight test data or FDR data) to ensure consistency of position, speed, and acceleration data.

## C. Baseline Simulation

A baseline simulation recreation of the accident flight was started just as the airplane turned onto the runway and the throttles were advanced, and the simulation was stopped at the end of the FDR data. Because the simulation can calculate the response of the airplane to control inputs, a set of control input time histories (column, wheel, and rudder movements) can be determined that results in the simulation following the same path as the accident airplane. It is important to note that this process does not use the control or surface position data recorded on the FDR, only the path information (e.g. accelerations, attitude and altitude).

Comparisons between the recorded FDR data and the simulation time history data are provided for longitudinal and lateral/directional data in Figures Figure 1.16.21 and Figure 1.16.2-2 respectively.

Figure 1.16.2-1 - FDR and Simulation Match Data - Longitudinal Axis

Figure 1.16.2-2 - FDR and Simulation Match Data - Lateral/Directional Axis

An examination of the baseline simulation revealed that the path of the accident airplane is consistent with the recorded motion of the control surfaces. Specifically, the extreme bank attitude that occurs towards the end of the flight is consistent with recorded motion of the ailerons.

The simulation also revealed that the motion of the control surfaces is consistent with the recorded motion of the control inputs, with the exception of control wheel

## D. Hypothetical Faults resulting in a rolling moment

Several hypothetical airplane system faults were examined to determine if any could have resulted in the right roll behavior recorded on the FDR. These faults included:

- Uncommanded deployment of the \#1 slat
- Uncommanded spoiler deflection to full travel (hardover)
- A spoiler disconnected from its actuator (spoiler float)
- Flap asymmetry
- Thrust asymmetry
- Unrecorded rudder motion

The hypothetical faults listed above are similar in that they each create a rolling moment unrelated to the position of the ailerons that will cause the airplane to bank. That is to say, if one of these faults had occurred, the path of the airplane would have differed from that predicted by the recorded position of the ailerons.

## E. Multi-Purpose Engineering Cab Simulator

Additional tests were conducted at Boeing's multi-purpose engineering cab simulator or M-Cab. The M-Cab is similar to a flight crew training simulator in that it consists of a realistic flight deck mounted on a movable base. The M-Cab includes a visual system providing out-the-window views to the flight crew. Because the M-Cab is used to simulate the flight deck of many different Boeing models, actual flight instruments are not used. Instead, a large LCD display is programmed to simulate the flight instrument displays. Examples of the M-Cab's flight instrument displays for the 737-300 are shown in section 1.6.2.
Major differences between the M-Cab and a typical flight crew training simulator are listed below.

- The M-Cab can simulate different model airplanes including 707, 727, 737, $747,757,767$, and 777.
- The M-Cab can be reprogrammed to simulate a wide variety of hypothetical aircraft system faults.
- The M-Cab can be "backdriven" to reproduce recorded data, such as the simulation match to the accident flight discussed in section 1.16.2. In addition, the backdrive can be interrupted at any point with a transition to normal simulator operation at the current flight conditions. This capability (known as "breakout" allows pilots in the simulator to attempt to recover the airplane from various points in the accident profile.
- The operation of the M-Cab is recorded at a high sample rate The M-Cab was used to recreate the accident flight as well as to study a number of hypothetical airplane system faults.

## F. Tests conducted in the M-Cab

The M-Cab was used to examine some of the faults mentioned above (item D), as well as a number of other hypothetical faults affecting the lateral control system or the autopilot system. M-Cab tests included:

- Backdrive of FDR data
- Backdrive with breakout at 02:44:44
- Backdrive with breakout at 02:44:56
- Spoiler float
- Uncommanded aileron trim to full authority
- Uncommanded aileron trim to half authority
- Autopilot servo actuator hardover without force limiter engaged
- Autopilot servo actuator hardover with force limiter engaged
- Autopilot servo actuator hardover with pressure regulator and relief valve inoperative

The spoiler control drum jam and control wheel shaft jam scenarios were accomplished by "background" simulation analysis.

The tests in the M-Cab were conducted with an out-the-window scene equivalent to that available to the accident pilots with the following exceptions:

1) The visibility conditions simulated (ceiling and visibility unlimited at night with no moon) were those reported at the airport at the time of the accident. Actual visibility conditions on the flight deck at the time of the accident are unknown.
2) The ground in the vicinity of Sharm el-Sheikh was depicted through the use of satellite photography taken during daylight hours. It did not represent the nighttime scene of street lights, building lights, etc. against an otherwise dark landscape.
1.16.1.0. General Overview of Boeing Process_Kinematic Consistency:
(CairoMarch04Slides March Progress Meeting - Cairo.pdf)
(Kincon and Simulation (public release).ppt)

## FDR Data

- Accelerations and Euler angles recorded on the FDR uniquely determine the path of the airplane
- Accelerations
- Vertical
- Longitudinal
- Lateral
- Euler angles
- Pitch
- Roll
- Heading
- Additional parameters describe path
- e.g. altitude, ground speed, drift angle

## Problem

- Some FDR data may be inconsistent with other FDR data
- Example:
- Integrating longitudinal acceleration during a takeoff roll results in groundspeed. The calculated value may differ from the recorded value.
- Solution:
- Add an offset to the acceleration such that the calculated groundspeed matches the recorded groundspeed.

737-300 SU-ZCF

## Kinematic Consistency

- Kinematic consistence is a process that adds a bias to the recorded accelerations so that the integrated path matches the recorded path
- i.e. calculate $c_{1}$ such that

$$
\begin{aligned}
& v=\int\left(a+c_{1}\right) d t \\
& \text { where } \\
& v=\text { groundspeed } \\
& a=\text { longitudinal acceleration }
\end{aligned}
$$

Altitude

## Kinematic Consistency Results

## Kinematic Consistency Results

## Kinematic Consistency Results

## Kinematic Consistency Results

Confidential Investigative Information

## Kinematic Consistency Results

## Kinematic Consistency Results

## Kinematic Consistency

- Note:
- The kinematic consistency process does not make any assumptions about the aerodynamic properties of the airplane
- In fact, the process can be applied to any moving object

## Simulation

- Once the kinematically consistent accelerations and Euler angles have been calculated, an aerodynamic simulation of the airplane is used to reconstruct the flight path
- Time-step integration is used to calculate the motion of the airplane from one step to the next

$$
\begin{gathered}
v_{t 1}=v_{t 0}+a_{t 0} \Delta t \quad x_{t 1}=x_{t 0}+v_{t 0} \Delta t \\
L i f t=\frac{1}{2} \rho v^{2} S C_{L} \\
C_{L}=f(\alpha, v, \text { flaps, gear, control surfaces, } \ldots)
\end{gathered}
$$

## Sensitivity Example

-Accident flight is approximately 147 seconds long
-Simulator match of altitude differs by approximately 200 feet
-Sensitivity analysis for straight and level flight 147 seconds long
$F=M A$ or $A=\frac{F}{M}$
For vertical axis $\quad \ddot{z}=\frac{L-W}{W} \longrightarrow z=\iint \frac{L-W}{W} d t^{2}$

For constant weight $\quad z=\left.g \frac{L-W}{W} \frac{t^{2}}{2}\right|_{t_{1}} ^{t_{2}}$

## Sensitivity Example

For constant weight $\quad z=\left.g \frac{L-W}{W} \frac{t^{2}}{2}\right|_{t_{1}} ^{t_{2}}$

Assume altitude error is result of incorrect lift

$$
\Delta z=g \Delta \frac{L-W}{W} \frac{t^{2}}{2}
$$

Solve for $\Delta \mathrm{L} \quad \Delta \frac{L-W}{W}=\frac{2 \Delta z}{g t^{2}} \quad \Delta L=\frac{2 W \Delta z}{g t^{2}}$

Therefore-

$$
\Delta L=\frac{2(113630 \mathrm{lb})(200 \mathrm{ft})}{32.2 \frac{\mathrm{ft}}{\mathrm{sec}^{2}}(147 \mathrm{sec})^{2}}=65 \mathrm{lbs}
$$

A 65 lb error in calculated lift will result in a altitude error of 200 ft after 147 seconds.

## Simulation Differences

The 737-300 simulation model represents a nominal airplane with nominal engines.

Small offsets between the nominal simulation airplane and an individual airplane in the fleet are common due to differences in rigging, engine wear, etc.

## Pass Through Data

For Flash Airlines simulation -

- Stabilizer was adjusted to account for control column bias ( $2.9^{\circ}$ offset)
- Throttle level position was adjusted to improve match of airspeed and altitude

## M Cab Recovery (Piloted Recovery.xls)

Flash Airlines
M-Cab Recoveries

Flash Airlines M-Cab Recoveries

Simulation Scenario (Simulation Scenario Status20 Sep.,04.xls)

| Flash Airlines Requested Simulation Scenarios |  |  | Last Updated 7 Sept 04 |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | 29-Jul-04 | 20-Sep-04 |  |
| No. | Scenario | M-Cab Status | Comments | MCA Comments | MCA Comment | Presentation |
| 1 | Use M-cab like a training simulator (manual flight with no backdrive) | Available now | The M-cab is capable of performing like a training simulator. However, it does not have an "instructor's station" to insert preprogrammed malfunctions like many training simulators do. Therefore, if pre-programmed malfunctions are desired in the M cab, advance notice is required to ensure the correct routines can be loaded and available. | OK <br> MCA will advise if any such pre-programmed malfunctions are desired. | OK | Boeing |
| 2 | Backdrive of accident flight (from FDR data) | Available now | The full backdrive from the FDR data is available. A "breakout" switch will be installed that will allow manual pilot inputs at any point in the scenario. | OK | OK | Boeing |
| 3a | Slat extend (mid) fault | In work | No aero extend data |  |  | Boeing |
| 3b | Slat extend (full) fault | In work | This scenario will be available in the cab. It is the same scenario for which plots were provided in March at the Cairo meeting, except that we will insert the fault at flaps up. |  | MCA requests to perform fault insertion simultaneously with breakout and then attempt to fly accident flight path. The intention is to compare FDR aileron to aileron required to fly accident profile with fault. | Boeing |
| 4 | Spoiler hardover fault | In work | Same as \#3b except at time 92444 |  | MCA requests that fault be inserted at $\mathrm{A} / \mathrm{P}$ engage (92415) | Boeing |
| 5 | Spoiler float fault | In work | Same as \#3b except at time 92444 |  | MCA requests that fault be inserted at $\mathrm{A} / \mathrm{P}$ engage (92415) | Boeing |
| 6 | Slat "float" (assumed actuator detached and/or jammed/cocked slat) | Not available | The position of a floating slat is determined by the airload on the slat and friction within the system. We do not currently have that data available for the accident flight airspeed and altitude conditions. The airloads will either extend the slat, retract the slat, or will be insufficent to overcome system friction. Therefore, we believe the airplane level roll response will be bounded by the reponse to a slat fully extended fault such as \#3a above. <br> We are currently searching for additional aero data as requested by the MCA. <br> We have not been able to locate any additional aero data requested by the MCA. | Is there any additional aero data available for the effects of slats at other positions (i.e. between up and mid, between mid and full, or cocked)? | OK, Must be done or at least mid posn. | Boeing |
| 7 | Hardover on one aileron PCU | In work | A hardover of one aileron PCU will result in both aileron PCUs commanding full aileron, spoiler and control wheel hardover. We intend to demonstrate this scenario in the same manner as \#3a above by inserting the fault at time 92444. | OK | OK | Boeing |
| 8 | Aileron trim runaway | Available now | Aileron trim runaway can be simulated by manually moving the aileron trim control in the cab during manual flight. This can be done as part of \#1 above. | OK | OK | Boeing |
| 9 | A/P with MCP erroneous selected heading | In work | This scenario will result in the autopilot flying to the erroneous selected heading. This scenario can be simulated initializing the simulator at time 92395, then running open loop. At that point, the autopilot can be engaged and the desired "erroneous" selected heading can be entered on the MCP. | OK | OK | Honeywell |
| 10a | A/P with MCP Selected Heading knob mechanically inoperative, such that it does not transfer pilot commands. (Selected heading window and output to FCC constant regardless of knob movement) | Not required | This scenario has the same effect as \#9 above and can be simulated in the same way. |  | OK | Honeywell |
| 10b | A/P with one or more segments in the MCP selected heading LCD window inoperative leading to improper indicaiton (e.g. displaying 6 instead of 8 ) | Not required | The result of this fault will be that the apparent value in the heading window can be different than the value transmitted to the EADI for display of the heading bug and to the FCC for use in autopilot heading select mode. Although we will not be able to simulate a different value in the selected heading window, we believe that this fault can be simulated in the same way as \#9 above. |  | OK | Honeywell |

| 11 | A/P Actuator hardover | In work | This scenario will result in a "hardover" to the autopilot actuator authority limit ( 60 deg with the autopilot force limited not engaged). We can simulate this scenario by introducing the fault and "breaking out" simultaneously at 92415 ( $\mathrm{A} / \mathrm{P}$ initial engage) | OK | OK | Boeing |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 12a | A/P Actuator ARM Solenoid valve failed open with $A / P$ disconnected | Not required | With the arm solenoid open, the autopilot mod piston can move in response to FCC commands, but as the detend solenoid is not open, the mod piston is not coupled to the ailerons and the $\mathrm{A} / \mathrm{P}$ actuator cannot command aileron motion. We do not believe it is necessary to simulate this secenario. |  | OK | Boeing |
| 12b | A/P Actuator Detent Solenoid failed open with A/P disconnected | Not required | The arm and detent solenoids are in series. If the arm solenoid is closed, no hydrualic fluid is available to allow the detent pistons to couple the mod piston to the ailerons. The A/P actuator cannot command aileron motion. If this fault exists when the autopilot is trying to engage, the engagement may occur with a jolt as the mod piston would be coupled to the ailerons before the position synchronization is complete. We do not believe it is necessary to simulate this scenario. |  | OK | Boeing |
| 12c | A/P Actuator both arm and detent solenoid open with $\mathrm{A} / \mathrm{P}$ disconnected | Not required | This is the normal condition when the autopilot is engaged. The transfer valve spool moves the mod piston moves in response to commands from the FCC and the detent pistons are pressurized to couple the actuator to the ailerons. If the autopilot is not engaged, the FCC commands the tranfer valve to hold the autopilot actuator in the neutral (ailerons faired) position. Normal autopilot breakout is still available to override the autopilot. Without pilot intervention, the net result would be the same as letting go of the wheel and letting it center. We do not believe it is necessary to simulate this condition. |  | OK, Must be done | Boeing |
| 12d | A/P Actuator triple fault (arm and detent solenoid open, transfer valve jam off center) | See \#11 | This triple fault will result in an $\mathrm{A} / \mathrm{P}$ actuator hardover. The force limit of the actuator still operates normally. The hardover condition is the same as \#11 above. |  | OK | Boeing |
| 12e | A/P Actuator quadruple fault (arm and detent solenoid open, transfer valve jam, pressure regulator jam) | See \#11 | This quadruple fault will result in an $\mathrm{A} / \mathrm{P}$ actuator hardover. Because the pressure regulator is jammed, the relief valve operates and limits detent piston pressure. The wheel force required to overcome the actuator increases from 16 lbs of wheel to approximately 20 lbs of wheel. |  | OK, transfer valve jamed at different posn | Boeing |
| 12f | A/P Actuator quadruple fault (arm and detent solenoid open, transfer valve jam, relief valve jam) | See \#11 | This quadruple fault will result in an $\mathrm{A} / \mathrm{P}$ actuator hardover. Although the relief valve is jammed (stuck to the pressure regulator slide), the pressure regulator limits detent piston pressure to the normal level. The wheel force required to overcome the actuatoris the normal 16 lbs of wheel. |  |  | Boeing |
| 12g | A/P Actuator quintuple fault (arm and detent solenoid open, transfer valve jam, pressure regulator and pressure relief valve) | In work | This quintuple fault will result in an $\mathrm{A} / \mathrm{P}$ actuator hardover. In this scenario, neither the pressure regulator nor the relief valve can reduce the detent piston pressure which reaches hydrualic system pressure ( 3000 psi ). Wheel force required to overcome the actuator increases from 16 lbs of wheel to approximately 80 lbs of wheel. |  | MCA requests to observe this fault (feel the forces) or the highest forces possible in the M-cab. | Boeing |
| 13 | A/P with IRU shutdown | Not required | The response of the autopilot to an IRU shutdown is to disconnect. We do not believe it is necessary to simulator this scenario. | OK | OK | Honeywell |
| 14 | A/P with Erroneous R IRU output of straight and level flight during bank (no NCD or fail warn transmitted) | In work | The autopilot will command aileron to its authority limit (20 deg with aileron force limiter). If the airplane heading crosses the selected heading the autopilot command will reverse. MCab simulation will not accurately reflect the wheel forces in this situation. | OK | OK | Honeywell |
| 15a | A/P with Erroneous L IRU output of roll rate with all other parameters correct (separately and then see if possible to do at same time as above fault) | Not required | Autopilot A does not use L IRU roll rate as an input. This fault has no effect on the operation of autopilot A. | MCA requests this be changed to R IRU output of NCD for roll rate. | OK | Honeywell |
| 15b | A/P with R IRU output of NCD for roll rate | Not required | The response of the autopilot to R IRU output of NCD for roll rate is to disconnect. We do not believe it is necessary to simulate this scenario. |  | OK | Honeywell |
| 16 | Autopilot spoiler sensor fault (erroneous value) | Not applicable to M-Cab | The sensed value of spoiler angle is only used by the autopilot when the flaps at 30 or beyond. This fault would have no effect on the operation of the autopilot for the accident flight. | OK | OK | Honeywell |

Simulation Scenario (Simulation Scenario Status 27-30 Sep, 04.xls)

| 4b | Spoiler mid extend jam | Requested | No |  |  |  |
| 5 | Spoiler float fault | In work | No | Same as \#3b except at time 92444 | MCA requests that fault be inserted at $\mathrm{A} / \mathrm{P}$ engage (92415) | Boeing |
| 6 | Slat "float" (assumed actuator detached and/or jammed/cocked slat) | Not available |  | The position of a floating slat is determined by the airload on the slat and friction within the system. We do not have aero data available for the accident flight airspeed and altitude conditions. The airloads will either extend the slat, retract the slat, or will be insufficent to overcome system friction. Therefore, we believe the airplane level roll response will be bounded by the reponse to a slat fully extended fault such as \#3b above. | OK | Boeing |
| 7 | Hardover on one aileron PCU | In work |  | A hardover of one aileron PCU will result in both aileron PCUs commanding full aileron, spoiler and control wheel hardover. We intend to demonstrate this scenario in the same manner as \#3b above by inserting the fault at time 92444. | OK | Boeing |
| 8 | Aileron trim runaway | Available now | Yes | Aileron trim runaway can be simulated by manually moving the aileron trim control in the cab during manual flight. This can be doneby breaking out at 92444 and manually inputting aileron trim. | OK | Boeing |
| 9 | A/P with MCP erroneous selected heading | In work |  | This scenario will result in the autopilot flying to the erroneous selected heading. This scenario can be simulated initializing the simulator at time 92395, then running open loop. At that point, the autopilot can be engaged and the desired "erroneous" selected heading can be entered on the MCP. | OK | Honeywell |
| 10a | A/P with MCP Selected Heading knob mechanically inoperative, such that it does not transfer pilot commands. (Selected heading window and output to FCC constant regardless of knob movement) | See \#9 |  | This scenario has the same effect as \#9 above and can be simulated in the same way. | OK | Honeywell |
| 10b | $\mathrm{A} / \mathrm{P}$ with one or more segments in the MCP selected heading LCD window inoperative leading to improper indicaiton (e.g. displaying 6 instead of 8) | See \#9 |  | The result of this fault will be that the apparent value in the heading window can be different than the value transmitted to the EADI for display of the heading bug and to the FCC for use in autopilot heading select mode. Although we will not be able to simulate a different value in the selected heading window, we believe that this fault can be simulated in the same way as \#9 above. | OK | Honeywell |
| 10c | A/P with MCP internal processor or MUX fault resulting in dissimilar values between the selected heading window and the selected heading command to the FCC | See \#9 |  | This scenario has the same effect as \#10b and can be simulated in the same manner as \#9. | OK | Honeywell |

| 11 | A/P Actuator hardover | In work | This scenario will result in a "hardover" to the autopilot actuator authority limit ( 60 deg with the autopilot force limited not engaged). We can simulate this scenario by introducing the fault and "breaking out" simultaneously at 92415 (A/P initial engage) | OK | Boeing |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 12a | A/P Actuator ARM Solenoid valve failed open with $\mathrm{A} / \mathrm{P}$ disconnected | Not applicable to M-Cab | With the arm solenoid open, the autopilot mod piston can move in response to FCC commands, but as the detend solenoid is not open, the mod piston is not coupled to the ailerons and the $\mathrm{A} / \mathrm{P}$ actuator cannot command aileron motion. We do not believe it is necessary to simulate this secenario. | OK | Boeing |
| 12b | A/P Actuator Detent Solenoid failed open with A/P disconnected | Not applicable to M-Cab | The arm and detent solenoids are in series. If the arm solenoid is closed, no hydrualic fluid is available to allow the detent pistons to couple the mod piston to the ailerons. The A/P actuator cannot command aileron motion. If this fault exists when the autopilot is trying to engage, the engagement may occur with a jolt as the mod piston would be coupled to the ailerons before the position synchronization is complete. We do not believe it is necessary to simulate this scenario. | OK | Boeing |
| 12c | A/P Actuator both arm and detent solenoid open with $\mathrm{A} / \mathrm{P}$ disconnected | Not applicable to M-Cab | This is the normal condition when the autopilot is engaged. The transfer valve spool moves the mod piston moves in response to commands from the FCC and the detent pistons are pressurized to couple the actuator to the ailerons. If the autopilot is not engaged, the FCC commands the tranfer valve to hold the autopilot actuator in the neutral (ailerons faired) position. Normal autopilot breakout is still available to override the autopilot. Without pilot intervention, the net result would be the same as letting go of the wheel and letting it center. We do not believe it is necessary to simulate this condition. | OK | Boeing |
| 12d | A/P Actuator triple fault (arm and detent solenoid open, transfer valve jam off center) | See \#11 | This triple fault will result in an A/P actuator hardover. The force limit of the actuator still operates normally. The hardover condition is the same as \#11 above. | OK | Boeing |
| 12e | A/P Actuator quadruple fault (arm and detent solenoid open, transfer valve jam, pressure regulator jam) | In work | This quadruple fault will result in an $\mathrm{A} / \mathrm{P}$ actuator hardover. Because the pressure regulator is jammed, the relief valve operates and limits detent piston pressure. The wheel force required to overcome the actuator increases from 16 lbs of wheel to approximately 20 lbs of wheel. | OK | Boeing |
| 12f | A/P Actuator quadruple fault (arm and detent solenoid open, transfer valve jam, relief valve jam) | See \#11 | This quadruple fault will result in an $\mathrm{A} / \mathrm{P}$ actuator hardover. Although the relief valve is jammed (stuck to the pressure regulator slide), the pressure regulator limits detent piston pressure to the normal level. The wheel force required to overcome the actuatoris the normal 16 lbs of wheel. |  | Boeing |
| 12g | A/P Actuator quintuple fault (arm and detent solenoid open, transfer valve jam, pressure regulator and pressure relief valve) | In work | This quintuple fault will result in an $\mathrm{A} / \mathrm{P}$ actuator hardover. In this scenario, neither the pressure regulator nor the relief valve can reduce the detent piston pressure which reaches hydrualic system pressure ( 3000 psi ). Wheel force required to overcome the actuator increases from 16 lbs of wheel to approximately 80 lbs of wheel. | MCA requests to observe this fault (feel the forces) or the highest forces possible in the M-cab. | Boeing |
| 13 | A/P with IRU shutdown | Not applicable to M-Cab | The response of the autopilot to an IRU shutdown is to disconnect. We do not believe it is necessary to simulator this scenario. | OK | Honeywell |
| 14 | A/P with Erroneous R IRU output of straight and level flight during bank (no NCD or fail warn transmitted) | In work | The autopilot will command aileron to its authority limit (20 deg with aileron force limiter). If the airplane heading crosses the selected heading the autopilot command will reverse. M-Cab simulation will not accurately reflect the wheel forces in this situation. | OK | Honeywell |
| 15a | A/P with Erroneous L IRU output of roll rate with all other parameters correct (separately and then see if possible to do at same time as above fault) | Not applicable to M-Cab | Autopilot A does not use L IRU roll rate as an input. This fault has no effect on the operation of autopilot A. | OK | Honeywell |
| 15b | A/P with R IRU output of NCD for roll rate | Not applicable to M-Cab | The response of the autopilot to R IRU output of NCD for roll rate is to disconnect. We do not believe it is necessary to simulate this scenario. | OK | Honeywell |
| 16 | Autopilot spoiler sensor fault (erroneous value) | Not applicable to M-Cab | The sensed value of spoiler angle is only used by the autopilot when the flaps at 30 or beyond. This fault would have no effect on the operation of the autopilot for the accident flight. | OK | Honeywell |
| 17 | Failure of bank angle limit function in autopilot | See \#14 | No condition has been identified that could lead to this fault without causing an FCC shutdown. However, if it did occur, the extreme result would be an autopilot actuator hardover as the FCC seeks to achieve an excessive roll angle. As the aileron force limiter is engaged, the hardover would result in wheel offset to 20 degrees. | OK | Honeywell |
| 18 | Other FCC internal faults | See \#11 or \#14 | No condition has been identified that could lead to this fault without causing an FCC shutdown. However, if it did occur, the extreme result would be an autopilot actuator hardover. As the aileron force limiter is engaged, the hardover would result in wheel offset to 20 degrees (AFL eng) or 60 deg (AFL not engaged). | OK | Honeywell |
| 19 | FD behavior with erroneous selected heading data from MCP | In work | We intend to implement this scenario the as part of \#21 below. The desired "erroneous" selected heading can be entered using the MCP. | OK | Boeing |
| 20 | FD behavior with erroneous roll rate data from IRU | In work | The roll rate error will effectively reduce or increase the maximum bank angle for the maneuver (depending upon the sign of the roll rate error). It will also result in a steady state heading error once the turn was complete. In order for the aileron command to remain at zero the heading error and roll rate error will cancel. | OK | Honeywell |

1.16.1.4. Simulated Failures:

HEA_PQ294_Simulated_Failures Spoilers, LE Slats.pdf (FDR-norm simulation-simulation with spoilers failures)
Right outboard flight spoilers (\#7) Hardover simulation (hardover starts at 92391)

Left outboard flight spoilers (\#2) Hardover simulation (hardover starts at 92391)

Right outboard flight spoilers (\#7) Float simulation (floats starts at 92391)

Left outboard flight spoilers (\#2) Float simulation (floats starts at 92391)

Critical right wing leading edge slat \# 6 extends

Critical left wing leading edge slat \# 1 extends

Scenario 10 - Spoiler wing cable jam (Spoiler wing cable jam) offset of the neutral position at time 92450 (maximum wheel deflection).and clears at 92472

Lateral Axis, simulated right wing spoiler cable jam

Scenario 10a - F/O wheel jam (F/O wheel jam) offset of the neutral position at time 92450 (maximum wheel deflection). and clears at 92472

Longitudinal Axis, simulated F/O's wheel jam:

Lateral Axis, simulated F/O’s wheel jam:

## 65-44761-21 Aileron PCU

Rod end fitting missing Main ram fractured

Tailstock
missing

## 65-44761-21 Aileron PCU

## Hydraulic Fittings

- Hydraulic fittings found broken
- Provides a path for sea water and other contaminants to enter the actuator

## Hydraulic Schematic

## Servo Valve Components

## Computed Tomograph Scan

Computed Tomograph Scan

## Filter

- Filter cap and filter element removed
- Fluid sample and filter retained for chemical analysis

## Bypass Valve

- Some corrosion and contamination on bypass valve sleeve
- Samples retained for chemical analysis

- Metal sliver found on outside of sleeve
- Origin uncertain, retained for chemical analysis

## Input Shafts

- Linkage cavity cover removed
- Some contamination noted in linkage cavity - samples taken for analysis
- View shows end of inner shaft and shaft and mating ends of servo valve slides

## Input Shafts

- Inner input shaft pressed out (required removal force much higher than normal)
- View shows outer shaft and mating ends of servo valve slides (inner shaft has been removed)

## Input Shafts

- Both shafts found to be bent
- Some corrosion found on shaft bearings, but none on shafts
- Deformed shafts consistent with high removal forces

## Servo Valve

- Outer shaft rotated to allow removal of servo valve
- Axial load of 29 lbs applied to primary sleeve - no movement noted
- After removal, slides remain jammed

## Servo Valve Cross Section

Computed Tomograph Scan

## Servo Valve

- Decision made to discontinue disassembly of servo valve (driving out slides could cause damage to surfaces)
- If deemed necessary, servo valve can be sectioned by electro-machining discharge (EDM).

Responses to Airplane System Queries
Flash Airlines 737 SU-ZCF Accident at Sharm el Skeikh - 3 Jan 04

## Questions from the MCA on 25 Jan 04

A1) Why did the autopilot disengage?
Answer: There are three possible reasons why the autopilot disengaged: the engage synchronization (actuator to surface) failed to complete; the engage hold interlocks were not satisfied; or it was mamually disconnected. Based on the data recorded on the FDR, we are not able to pinpoint which of these caused the autopilot to disengage. Additional information on the details of the interlocks and their operation are provided in the Airplane Maintenance Manual section 22-11-01. (1)

A2) What is the effect of hydraulic systems failures on the flight controls?
Answer: The hydraulic system arrangement for the 737-300 flight controls is provided in the attached figure. This figure shows which functions would be lost in the event of either an A or B hydraulic system failure.

A3) What does the FD command? Roll rate? Bank angle?
Answer: The Flight Director (FD) provides a bank angle command that is primarily a function of selected heading, airplane heading, airplane roll angle, and airplane roll rate. (1)

A4) Please provide the FMEA for the 737-300 autopilot and flight controls related to the roll axis.
Answer: The following documents were mailed to the NTSB, MCA and BEA:
D6-14070 737-300 Lateral Failure Analysis (7MB)
D6-37432 737-300 Autopilot Failure Analysis (20MB)
A5) What does the flight director do when the airplane bank angle exceeds the selected bank angle limit?
Answer: It will produce a command to fly back to the desired bank angle. (1)

A6) What does the flight director do when the airplane roll rate exceeds the intended roll rate?
Answer: It will produce a command to fly back to the desired bank angle. (1)

[^13]A7) What are the aileron travel rates with various hydraulic system availability?
Answer: The aileron PCUs are significantly oversized. Because of this, aileron travel rates are not a function of hydraulic system availability - i.e. aileron travel rates are not significantly different whether either or both hydraulic system is pressurized. For reference, the no load rate is approximately 54 degrees per second of aileron.

A8) How is Selected Heading recorded on the FDR if it is being turned while the knob is being moved)
Answer: The FCC transmits the selected heading value to the DFDAU at a rate of 20 times per second. The DFDAU then takes the latest value once each 64 seconds and sends it to the DFDR for recording. Thus, if selected heading is dynamically changing when the once-per-64seconds sample is taken, it will record the selected heading value at the time the sample was taken.

A9) Is the hydraulic pump capable of outputting 5000 psi of pressure?
Answer: The following two failures are required in order to reach $5000 \mathrm{psi}: / 1 /$ the pump compensator is failed open (full flow), and /2/ the system relief valve failed closed. For the hydraulic system pressure display, in-range is considered to be from -100 to 4,100 psi, so 5000 psi would be out of range. If the system were to actually go to 5000 psi, the affected hydraulic pressure display (on the EIS) would slew to its lower stop; hold for 2 seconds then the pointer would disappear and dashes would appear in the display.

A10) What caused the Master Caution discrete late in the flight?
Status: The Master Caution discrete occurs at time 92465 in the FDR data file received by Boeing. There are over 40 inputs that could have caused this discrete to be set. We are still evaluating the possible causes of the setting of this discrete, and expect to have an update for the next progress meeting in Cairo. We did notice that the Master Caution discrete was set several times on previous flights. Airplane records, such as technical log entries, may record the reason for previous Master Caution events. These records may help isolate why the Master Caution was set at time 92465 in the accident flight.

[^14]Responses to Airplane System Queries
Flash Airlines 737 SU-ZCF Accident at Sharm el Skeikh - 3 Jan 04

B1) Correlation between control inputs and flight control surface deflections, with special emphasis on the inconsistency of control wheel and aileron surface deflection as indicated by the FDR.
Answer: A kinematic consistency check and a simulator proof-of-match is being accomplished on the accident data at Boeing. This work is still in progress; however, we have been able to make a few observations on the bias in control wheel position. There is a bias in control wheel position that shifts over time, and possibly a scaling issue. Both issues are being further analyzed for possible explanations. (1)

B2) Investigate the changes in aileron deflection bias.
Answer: The changes in aileron position bias are caused by the airload on the aileron reacting against the cable run in the wing between the aileron and aileron PCU. The bias in aileron position is due to aileron hinge moment which varies as a function of airspeed. (1)

B3) Investigate the cause(s) for the autopilot disconnect.
Answer: See response to question Al.
B4) Investigate the cause for HDG SEL disengage when the autopilot was engaged.
Answer: If the FD command is greater than 7 degrees at the time autopilot engagement is attempted, the roll mode will change from HDG SEL to CWS. According to the FDR data, this seems consistent with the probable flight director command which existed when $A / P$ engagement was initiated. (1)

B5) Investigate the possible failure modes of the Flight Director indicator. Status: $\quad$ This is being researched. We will have some preliminary data available to discuss during the next progress meeting in Cairo.

[^15]Responses to Airplane System Queries
Flash Airlines 737 SU-ZCF Accident at Sharm el Skeikh - 3 Jan 04

B6) Investigate availability of autopilot during the captain's requests for "autopilot, autopilot".
Answer: The autopilot will not initiate the engage sequence if the A/P engage interlocks are not satisfied (ref AMM 22-11-01 page 54). If the engage interlocks are not satisfied, the attempt to engage ( $A / P$ button push) will not be recorded on the FDR. In the case of the accident flight it's possible that forces on the column or wheel prevented the engage logic from being satisfied. Additional information on the details of the interlocks and their operation are provided in the Airplane Maintenance Manual section 22-11-01. (1)

B7) Investigate the effect of flight control surface failures for surfaces like spoiler deflections that are not recorded on the FDR.
Answer: The effects of various spoiler failures are being examined using kinematic simulations. These results are expected to be available for the next progress meeting in Cairo.

## Observations on EGT and Engine Oil Pressure Parameters

During the work in Cairo, it was noted that the EGT and engine oil pressure parameters did not appear to be working properly for either the left or right engines. All four of these parameters are defined in D6-55333 Appendix B and are found in word 61 of the 737-2 data frame, along with a number of other parameters which occupy the same locations. There are several variants of the 737-2 data frame depending upon whether the airplane is equipped with an electronic engine instrument system (EIS) or an electronic flight instrument system (EFIS). The subject airplane, SU-ZCF, was equipped with both and the resulting data frame variant is informally referred to as the 737-2EE data frame. Appendix B lists all variants of the data frame, including the multiple parameters that can be stored in word 61. The order of data selection, e.g. which parameters are actually to recorded in word 61 , is provided in the general notes of appendix B. In this case, the EFIS parameters have priority over the EIS parameters and EGT and engine oil pressure are not recorded. Thus, the attempted conversion of word 61 into EGT and engine oil pressure is not appropriate in the 737-2EE data frame. In the 737-2EE data frame, word 61 is used for a number EFIS mode selection discretes, which appear to be recorded properly on the FDR.
(1) We are preparing additional and more detailed technical information about the operation of the autopilot, flight director, and lateral control systems which will be available for discussion during the next progress meeting in Cairo.

## Lateral System-answers to questions

A2) What is the effect of hydraulic systems failures on the flight controls?
Answer: The hydraulic system arrangement for the 737-300 flight controls is provided in the attached figure. This figure shows which functions would be lost in the event of either an $A$ or $B$ hydraulic system failure.
A7) What are the aileron travel rates with various hydraulic system availability?
Answer: The aileron PCUs are significantly oversized. Because of this, aileron travel rates are not a function of hydraulic system availability. i.e. aileron travel rates are not significantly different whether either or both hydraulic system is pressurized. For reference, the no load rate is approximately 54 degrees per second of aileron.
B1) Correlation between control inputs and flight control surface deflections, with special emphasis on the inconsistency of control wheel and aileron surface deflection as indicated by the FDR.
Answer: A kinematic consistency check and a simulator proof of match is being accomplished on the accident data at Boeing. This work is still in progress, however; we have been able to make a few observations on the bias in control wheel position. There is a bias in control wheel position that shifts over time, and possibly a scaling issue. Both issues are being further analyzed for possible explanations. (1)

B2) Investigate the changes in aileron deflection bias.
Answer: The changes in aileron position bias are caused by the airload on the aileron reacting against the wing cable run between the aileron and aileron PCU. Therefore, the bias in aileron position is due to aileron hinge moment which varies as a function of airspeed. (1)
B7) Investigate the effect of flight control surface failures for surfaces like spoiler deflections that are not recorded on the FDR.
Answer: The effects of various spoiler failures are being examined using the Boeing simulation. These results are expected to be available for the next progress meeting in Cairo.
Boeing Proprietary

## Autopilot - Answers To Questions

Al) Why did the autopilot disengage?
Answer: There are three possible reasons why the autopilot disengaged: the engage synchronization (actuator to surface) failed to complete; the engage hold interlocks were not satisfied; or it was manually disconnected. Based on the data recorded on the FDR, we are not able to pinpoint which of these caused the autopilot to disengage. Additional information on the details of the interlocks and their operation are provided in the Airplane Maintenance Mamual section 22-11-01. (1)

B3) Investigate the cause(s) for the autopilot disconnect.
Answer: See response to question A1.

B6) Investigate availability of autopilot during the captain's requests for "autopilot, autopilot". Answer: The autopilot will not initiate the engage sequence if the $A / P$ engage interlocks are not satisfied (ref AMM 22-11-01 page 54). If the engage interlocks are not satisfied, the attempt to engage ( $A / P$ button push) will not be recorded on the FDR. In the case of the accident flight it's possible that forces on the column or wheel prevented the engage logic from being satisfied. Additional information on the details of the interlocks and their operation are provided in the Airplane Maintenance Manual section 22-11-01. (1)

## FD-answers to questions

A3) What does the FD command? Roll rate? Bank angle?
Answer: The Flight Director (FD) produces a roll and roll rate command to zero the error between the selected heading and the magnetic heading. (1)

A5) What does the flight director do when the airplane bank angle exceeds the selected bank angle limit?
Answer: It will produce a command to fly back to the desired bank angle. (1)
A6) What does the flight director do when the airplane roll rate exceeds the intended roll rate? Answer: It will produce a command to fly back to the desired bank angle. (1)

A8) How is Selected Heading recorded on the FDR if it is being turned while the knob is being moved)
Answer: The FCC transmits the Hdg Sel value to the DFDAU at a rate of 20 times per second. The DFDAU then takes the latest value once each 64 seconds and sends it to the $D F D R$ for recording. Thus, if Hdg Sel is dynamically changing when the once-per-64seconds sample is taken, it will record the Hdg Sel value at the time the sample was taken.

B4) Investigate the cause for Hdg Sel disengage when the autopilot was engaged.
Answer: If the FD command is greater than 7 degrees at the time autopilot engagement is attempted, the Heading Select mode will be reset and the roll mode will default to CWS. According to the FDR data, this seems consistent with the probable flight director command which existed when A/P engagement was initiated. (1)
Boeing Proprietary

## Other-answers to questions

A4) Please provide the FMEA for the 737-300 autopilot and flight controls related to the roll axis.
Answer: The following documents were mailed to the NTSB, MCA and BEA:
D6-14070 737-300 Lateral Failure Analysis (7MB)
D6-37432 737-300 Autopilot Failure Analysis (20MB)
A9) Is the hydraulic pump capable of outputting 5000 psi of pressure?
Answer: The following two failures are required In order to reach 5000 psi: /1/ pump compensator failed open (full flow), and /2/ system relief valve failed closed. For the hydraulic system pressure display, in-range is considered to be from -100 to 4,100 psi, so 5000 psi would be out of range. If the system were to actually go to 5000 psi, the affected hydraulic pressure display (on the EIS) would slew to it's lower stop; hold for 2 seconds then the pointer would disappear and dashes would appear in the display.

## A10) What caused the Master Caution discrete late in the flight?

Status: The Master Caution discrete occurs at time 92465 in the FDR data file received by Boeing. There are over 40 inputs that could have caused this discrete to be set. We are still evaluating the possible causes of the setting of this discrete, and expect to have an update for the next progress meeting in Cairo. We did notice that the Master Caution discrete was set several times on previous flights. Airplane records, such as technical log entries, may record the reason for previous Master Caution events. These records may help isolate why the Master Caution was set at time 92465 in the accident flight.

## Responses to Queries

Flash Airlines 737 SU-ZCF Accident at Sharm el Skeikh - 3 Jan 04

## Questions from 1 March 04

1) How is drift angle matched in KINCON with corrected accelerations? Response: Wheel-well based accelerometer data recorded on the FDR are integrated and converted into a ground speed vectors and altitude. Using IRU information, the ground speed vectors are converted into a drift angle and ground speed. The calculated altitude, drift angle and ground speed are then compared to the recorded altitude and the FMC's recorded drift angle and ground speed. Differences between the two sets of data are minimized by calculating a unique but constant acceleration bias for each axis. The biases are then applied to the recorded accelerometer data. The biases were calculated based on minimizing the error over the entire accident flight.
2) With the simulator match data vs FDR data, at the end of the flight when rolling back towards wings level, time 92470 thru the end of data, why does the FDR data show the oscillatory motion, but the simulator match does not?
Response: The simulator match is an iterative process in which the difference between the simulator behavior and the recorded FDR data is used as a feedback (with a specific gain) to revise the simulator control inputs. In general, a lower gain produces smoother control inputs (lower frequency content) while a higher gain is required to match highly dynamic maneuvers, but can produce significant noise. The gain used in this iteration was chosen to best match the behavior in the time period from 92337 to 92470 . Increasing the gain to match the highly dynamic portion of the flight after time 92470 would have introduced significant noise into the earlier portion of the simulation.
3) From FDR time 92470 thru the end of data, are the aileron rates seen on the FDR within the capability of the system (i.e. is it real)?
Response: Yes, the aileron rates seen at the end of the FDR data are within the capability of the system.
4) With respect to the FDR recorded wheel position data, the wheel bias in the air, just after takeoff, is different on the accident flight than the previous flight, Why? Response: The bias in the recorded control wheel signal appears to change on mumerous occasions. As noted in the earlier presentation material, the bias changes during the control wheel sweep prior to every takeoff. In addition, the bias appears to change during every climb out, typically between takeoff and flaps up. Furthermore, the bias also appears to change just prior to landing, either during descent or approach. See attached slides that show the changing wheel bias for the accident flight and the previous flight. Similar behavior is noted in all flights, including the first recorded landing, control sweep and takeoff from Abu Simbel. The behavior of the recorded FDR wheel signal appears consistent with a slipping synchro body.

## Responses to Queries

Flash Airlines 737 SU-ZCF Accident at Sharm el Skeikh - 3 Jan 04
5) What equation is Boeing using to convert raw data into EU for Wheel Position? Response: The conversion steps are as follows:

1. The raw data is first converted to a signed quantity using two's complement.
2. The signed counts (C) are converted to synchro degrees (S) using the formula: $S=C * 360 / 1024$
3. The synchro degrees $(S)$ are converted to degrees of wheel $(W)$ using the formula: $W=S * 150.7663958 / 180$

Additional Information: The control wheel sensor on this airplane is a synchro. The synchro signal is interpreted by the FDAU and passed to the flight recorded as counts. Different FDAUs interpret the synchro signal differently. SU-ZCF was equipped with a Sundstrand FDAU which interprets the synchro linearly. Other FDAU's (e.g. Teledyne) use a non-linear interpretation of synchro data. For Sundstrand FDAU's (and any other that interprets synchros linearly), the correct conversion for wheel data is a linear one such as the one shown above in step 2 . For a Teledyne FDAU, a non-linear conversion is required. This conversion is built into the RAPS program and is called "dc_TELEDYNE_SYNCHRO". It would not be appropriate to use this function for converting data from a Sundstrand FDAU, such as the SU-ZCF data. In examining the FFD file provided, it appears that this function is being used to convert control wheel data. This conversion will introduce some errors as shown in the attached plots.

The MCA also provide a sheet of paper titled "Analog Signal Description" dated 24 May 1991, with the notation "Project BS7372". The data in this sheet appears to match the D6-55333 data for the 737-2 data frame with 2 exceptions:

D6-55333 defines control wheel as a 10 bit signal. BS7372 lists the signal as a 12 bit signal. The lower two bits of the actual dataframe are used to discrete bits. If both these bits are set, than a wheel position error of $\sim 0.22$ degrees will result.

The scaling of the BS7372 differs by a small amount from that of D6-55333. Note: The BS7372 sheet lists separate "Breakpoints" in the data. These "break points" exist to account for the signed nature of the signal (it wraps around from maximum counts back to zero). The function of the "break point" in the BS7372 data is accomplished by the two's complement function listed above and that also exists in the RAPS conversion listed in the FFD file provided.

Responses to Queries Flash Airlines 737 SU-ZCF Accident at Sharm el Skeikh - 3 Jan 04
6) Please provide a schematic showing the dual concentric control valve in the aileron PCU, and how it attaches to the PCU input rod. Response: Schematics provided.
7) What bias springs are present on the PCU valve, and which direction are they biased?
Response: Schematics provided.
8) Is there any delay between the time the autopilot is disconnected and when the disconnect warning is issued.
Response: The MCP monitors the CMD and CWS discretes from the FCC and immediately sets the warning (light and aural) when an autopilot disconnect is detected.
9) What method does Boeing use to perform differentiation on flight data? Is there software available for purchase, or what is our algorithm?
Response: Without knowing the specifics of the differentiation in question, we can provide a very general answer. Because of the inherent noise associated with differentiation, Boeing tends to avoid differentiation of recorded signals where possible. In some cases, when differentiation is required, we have first modeled the recorded data with a curve fit known to have contimuous derivatives and then performed the differentiation on the fitted curve. In other cases, it is possible to take advantage of the known behavior of specific physical quantities and required relationships between different recorded signals when differentiation is required.

## Questions from 2 March 04

1) Relative to the photo at time 92415 , does the "CMD" and "CWS R" text appear on the EADI immediately when the cmd button is pushed or does it wait until the FCC has completed sync \& pressurize (i.e. connected to system)?
Response: Immediately when CMD is received from the MCP (button push or paddle lift) the FCC retransmits it to the EFIS processor for display on the EADI.
2) Would the roll FD bar really disappear when Hdg Sel was re-set during AP engage. The photo shows the bar gone because Hdg Sel had reset. Response: Yes, the FD bar will be biased out of view in this situation.
3) How does CWS R mode work?

Response: In CWS R, the autopilot will enter Heading Hold if the bank angle is less than or equal to 8 degrees or Bank Angle Hold if bank angle is greater than 8 degrees (if bank angle is greater than 30 it will return the airplane to 30 ).

Responses to Queries
Flash Airlines 737 SU-ZCF Accident at Sharm el Skeikh - 3 Jan 04
4) Relative to the photo at time 92470 , does the EADI have the feature that forces the blue/brown line to always be present, even in unusual attitudes?
Response: Yes, the forced blue/brown interface is present unless pitch attitude exceeds 85 degrees (up or down), at which point it is removed.

## Question /4/

HEA 737 SU-ZCF
Day 1

Preliminary Data
Created: March 01, 2001

Wheel bias shifts during landing at SSH, control sweep on ground at SSH, and takeoff on accident flight from SSH.

Preliminary Data Created: March O1, 2004

Wheel bias shifts during landing at VCE, control sweep on ground at SSH, and takeoff on previous flight from VCE.

Preliminary Data Created: March 01, 2004

Wheel bias shifts during landing at ABS, control sweep on ground at $A B C$, and first recorded takeoff from $A B S$.

## Autopilot - Answers To Questions

A1) Why did the autopilot disengage?
Answer: There are three possible reasons why the autopilot disengaged: the engage synchronization (actuator to surface) failed to complete; the engage hold interlocks were not satisfied; or it was manually disconnected. Based on the data recorded on the FDR, we are not able to pinpoint which of these caused the autopilot to disengage. Additional information on the details of the interlocks and their operation are provided in the Airplane Maintenance Manual section 22-11-01 . (1)

B3) Investigate the cause(s) for the autopilot disconnect.
Answer: See response to question A1.

B6) Investigate availability of autopilot during the captain's requests for "autopilot, autopilot". Answer: The autopilot will not initiate the engage sequence if the $A / P$ engage interlocks are not satisfied (ref AMM 22-11-01 page 54). If the engage interlocks are not satisfied, the attempt to engage (A/P button push) will not be recorded on the FDR. In the case of the accident flight it's possible that forces on the column or wheel prevented the engage logic from being satisfied. Additional information on the details of the interlocks and their operation are provided in the Airplane Maintenance Manual section 22-11-01.

Boeing Proprietary

- Q 1 - What can occur during the A/P engage sequence or after that would cause an aileron command change of $\mathbf{2 . 9 1}$ degrees during R CWS?

1. Input from wheel/ force sensors

- Pilot command
- Force sensor failure (CWS command rate to be evaluated against change)

2. Heading Hold submode entered

- Requires Roll Angle < $\mathbf{6}$ deg
- FDR data $=\mathbf{- 6 . 7}$ deg at autopilot engage in left IRU, right IRU used and data not known
- FDR aileron rates are above the A/P CWS command rates for Heading Hold

3. Misrigging or Failure of Quadrant Position Sensor or Actuator LVDT

- Actuator LVDT position information continuously monitored for failures
- Results in successful A/P synchronization when sensors match but surface and actuator to do match mechanically
- A/P operation did not reflect this in previous flights
- Q2 - Provide better description of engage "jolt" for scenario 13, Hypothetical Scenarios \# 2
- If this fault exists when the autopilot is trying to engage, the engagement may occur with minor wheel movement as the A/P piston would be coupled to the ailerons before the position synchronization is complete

Note: In-flight engage operation may differ from on ground engage due to aerodynamic loading on control surfaces versus only gravitation forces on surfaces on ground

## Answers to Questions from 31 Jan 2005 Meeting

- Q3 - Provide minimum time for disconnect given immediate A/P
synchronization with no detent pressure
- FCC receives Local Command from MCP Engage Logic when the A/ P CMD button is pressed
> Running Time: Start
- Detent Command logic detects synchronization and sets Aileron Detent Command output ( $\mathbf{1 0 0} \mathbf{~ m s ~ d e l a y ) ~}$
> Running Time : +100 ms
- Engage Logic receives Aileron Detent Pressure Command Wrap (50 ms delay) > Running Time : +150 ms
- Engage Logic does not receive valid Aileron Detent Pressure Switch data and removes power from MCP engage hardware, 3.5 ms delay)
> Running Time : +3.65 seconds
- MCP Engage Logic disconnect (minimum 45 ms , maximum 80 ms )
> Running Time : + $\mathbf{3 . 6 9 5}$ seconds
Minimum Time to A/P Disconnect with No Detent Pressure: 3.695 seconds

## Answers to Questions from 31 Jan 2005 Meeting

## Answers to Questions from 31 Jan 2005 Meeting

- Q4 - Provide relative probability for A/ P disconnect given signal invalid in scenario 10 b.

| Item | Interlock or Condition |  |  | Prevents Engage | Causes Disengage | Probability | Comment |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | A/P Stab Trim Cutout Switch Normal |  |  | Yes | Yes | Unlikely | Pilot action or switch failure while A/P in CMD |
| 2 | Main Electric Trim Switches (not pressed) |  |  | Yes | Yes | Unlikely | Pilot must attempt manual trimming while A/P in CMD |
| 3 | A/P Stab Trim Motor Speed Interlock (10 sec) |  |  | Yes | Yes | Unlikely | Failure must occur during 2 seconds while A/P in CMD |
| 4 | Aileron Force Limiter Authority Limit Interlock (10 sec ) |  |  | Yes | Yes | Unlikely | Failure must occur during 2 seconds while A/P in CMD |
| 5 | Aileron Force Limiter Clutch - disengage |  |  | Yes | No | FDR Data rules out | This interlock is only used prior to A/P engage |
| 6 | Aileron Force Limiter Clutch - engage in 0.5 sec |  |  | Yes | No | FDR Data rules out | FDR recorded disconnect timing too long for this disconnect case |
| 7 | A/P Disengage Switch |  |  | Yes | Yes | Possible | Pilot could have initiated disconnect |
| 8 | A/P Aileron Hydraulic Pressure Switch - stuck in pressurized state |  |  | Yes | No | FDR Data rules out | This would have prevented initial engagement and, after engage, not be detectable until after disengage |
| 9 | A/P Aileron Hydraulic Pressure Switch - pressure within 3.695 seconds after actuator detent solenoid engaged |  |  | No | Yes | FDR Data rules out | Minimum timing greater than FDR data by $\sim 0.1$ seconds |
| 10 | A/P Elevator Hydraulic Pressure Switch - stuck in pressurized state |  |  | No | Yes | FDR Data rules out | This would have prevented initial engagement and, after engage, not be detectable until after disengage |
|  | Possible cause |  |  |  |  |  |  |
|  | Unlikely cause FDR Mismatch | Italic Text | Flight | ondition | ismatch |  | Honeywell |

## Answers to Questions from 31 Jan 2005 Meeting

## Answers to Questions from 31 Jan 2005 Meeting

| Item | Interlock or Condition | Prevents Engage | Causes Disengage | Probability | Comment |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 21 | Less Than 5 lb Force On Control Column | Yes | No | FDR Data rules out | This only prevents engagement, will cause mode reversion to CWS with sufficient column force after A/P engage |
| 22 | Selected IRU Roll Angle Valid (norm - off side) | Yes | Yes | Unlikely | Failure must occur during 2 seconds while $A / P$ in CMD |
| 23 | Selected IRU Roll Rate Valid (norm - off side) | Yes | Yes | Unlikely | Failure must occur during 2 seconds while A/P in CMD |
| 24 | Selected IRU Pitch Angle Valid (norm - on side) | Yes | Yes | Unlikely | Failure must occur during 2 seconds while $A / P$ in CMD and FDR recorded valid Left IRU data |
| 25 | Selected IRU Pitch Rate Valid (norm - on side) | Yes | Yes | Unlikely | Failure must occur during 2 seconds while A/P in CMD and FDR recorded valid Left IRU data |
| 26 | A/P to CMD and R/A <400 Ft with LOC and GS engaged | No | Yes | FDR Data rules out | Only causes disconnect in approach mode |
| 27 | F/D in TO or GA, R/A Alt <400 feet and A/P to CMD | No | Yes | $\begin{aligned} & \text { FDR Data rules } \\ & \text { out } \end{aligned}$ | Only causes disconnect when TOGA mode selected |
| 28 | ADC CAS Not Valid (except in dual channel operation) | Yes | Yes | Unlikely | Failure must occur during 2 seconds while $A / P$ in CMD and FDR recorded valid Left DADC data |
| 29 | IRU Transfer | No | Yes | Unlikely | IRS transfer must occur in 2 seconds while A/P in CMD |
| 30 | A/P Engage Switch Swap | No | Yes | FDR Data rules out | FDR data indicates FCC B was not in CMD or CWS during the flight |

## Answers to Questions from 31 Jan 2005 Meeting

Possible cause
Unlikely cause
FDR Mismatch

- Q5 - What are the causes for reversion of Heading Select mode to Roll CWS (Control Wheel Steering) when the A/P is engaged?

1. Pressing the Heading Select pushbutton on MCP (when Heading Select mode active)
2. Applying greater than 10 lbs of wheel force after $\mathbf{A} P$ is Engaged

- A/P needs to be engaged in this case or the wheel force will prevent engagement

3. Losing True Airspeed (TAS) or Magnetic Heading validity

- Validity can be lost prior to A/P engage attempt without affecting mode
- Causes Roll F/ D bias out-of-view (BOV) when A/P is not engaged
- True Airspeed invalid will also cause Level Change to change to CWS P when A/P is engaged and Pitch F/D BOV when F/D On

4. F/ D Bar Command greater than 7 degrees of bank error (Performance Assessment Monitor (PAM) invalid)

- Based on FDR data, F/ D bank error > 7 degrees was present for more than 9 seconds prior to A/P engagement

```
Answers to Questions from 2 Feb 2005 Meeting
```

- What is the maximum rate of the Roll CWS command given a failure of the Wheel Force Transducer? (Scenario 9)
- 15.5 lbs maximum input into the Roll CWS control law based on hardware input scaling limit
- Command is multiplied by scaling factors and lagged prior to output for a maximum steady state output of 7.64 degrees of aileron (limited by wheel limit) about 0.77 seconds after fault occurs
- More than 3 lbs force sensor input prevents engagement, so failure in time sequence dependent with the 2.6 to 3.6 second CWS R engage period.

## Answers to Questions from 2 Feb 2005 Meeting

Aileron Command in CWS R with Wheel Force Sensors Failure

## Answers to Questions from 2 Feb 2005 Meeting

- What failures of the Flight Control Computer would cause the A/P to command a 3.64 degree aileron change in Roll CWS? (Scenario 9)

## Answers to Questions from 2 Feb 2005 Meeting

## Answers to Questions from 2 Feb 2005 Meeting

## Answers to Questions from 2 Feb 2005 Meeting

Note :This failure does not inhibit manual disconnect nor does it result in failure to disconnect with erroneous FDR disengaged indication. When this failure occurs, pilot can override erroneous command with normal autopilot override forces.

## Answers to Questions from 2 Feb 2005 Meeting

- Provide minimum time for disconnect given immediate A/P synchronization with no detent pressure (Scenario 10)
- FCC receives Local Command from MCP Engage Logic when the A/P CMD button is pressed
> Running Time: Start
- Detent Command logic detects synchronization and sets Aileron Detent Command output ( 100 ms delay, based on $\mathbf{0 . 0 0 5 \%}$ real time clock oscillator/ timer)
$>$ Running Time : $\boldsymbol{+ 1 0 0} \mathbf{~ m s} \pm \mathbf{0 . 0 0 5} \mathbf{~ m s}$
- Engage Logic receives Aileron Detent Pressure Command Wrap (50 ms delay, based on $0.005 \%$ real time clock oscillator/ timer)
$>$ Running Time : $\mathbf{+ 1 5 0} \mathbf{~ m s} \pm \mathbf{0 . 0 0 7 5} \mathbf{~ m s}$
- Engage Logic does not receive valid Aileron Detent Pressure Switch data and removes power from MCP engage hardware, $\mathbf{3 . 5} \mathbf{~ m s}$ delay, based on 50 ms task driven by $\mathbf{0 . 0 0 5 \%}$ real time clock oscillator timer)
$>$ Running Time : +3.65 seconds $\pm 0.0001825$ seconds
- MCP Engage Logic disconnect (minimum 45 ms , maximum 80 ms , no additional tolerance)
> Running Time : + $\mathbf{3 . 6 9 5}$ seconds $\pm 0.0001825$ seconds
Note: No input time penalty assumed through DMA I/ O controller: Assumes all I/ O exactly aligned in time with input/ output timing.

Minimum Time to A/P Disconnect with No Detent Pressure: 3.6948175 seconds

## Answers to Autopilot Questions from 2 Feb 2005

- What is the maximum time for the autopilot to disconnect given the detent solenoid is stuck open prior to A/P engagement? (Scenario 10)
- The time to the hydraulic pressurization and subsequent detent pressure switch reaction is a maximum of 50 ms
- DMA I/ O cycle maximum time delay of $536 \mu \mathrm{sec}$ for detent pressure input
- The detent logic of the engage interlocks is executed at $20 \mathrm{~Hz}(50 \mathrm{~ms})$ so a maximum of one frame delay due to just missing the input data.
- There is no software delay in reaction to detent pressure input by engage interlocks prior to detent command output.
- DMA I/ O cycle maximum time delay of $536 \mu \mathrm{sec}$ for disconnect command
- The MCP engage circuitry react in 45 to $\mathbf{8 0} \mathbf{~ m s}$ of the processor issuing a disconnect.

Note: This logic is depicted in the SP-300 DFCS Training Manual Volume 4 Sheet 54

Worst case time the FCC to disconnect for this case is 181.072 ms .

## Answers to Autopilot Questions from 2 Feb 2005

## Answers to Autopilot Questions from 2 Feb 2005

Scenario 5 \& 11 - Multiple FCC Failures Cause Erroneous F/D Command (Page 5)

```
Answers to Autopilot Questions from 2 Feb 2005
```

- Scenario 13 - Multiple FCC failures cause erroneous A/ P engage and erroneous command output
- FCCs CANNOTengage A/P on their own regardless of failure mode.
> MCP engage hardware is in control of autopilot engage. FCCs can only disable or enable MCP engage hardware.
> From page 9 of Scenario 13, since the FCC self-engages, the multiple FCC fault case, the IRU fault case, and the bank limit fault case (page 10) cannot be a function of FCC failure.

Answers to question_cairo meeting05.ppt
Boeing/ Honeywell proprietary information and will not be available for public use

## Action Item Response.ppt (Cairo meeting, 1-30-05 to 2-2-05), Boeing Action Items of 30 January (public release).ppt

Question 1
Does the aileron PCU bypass valve interconnect the extend and retract side of the main ram when no hydraulic pressure is available?
What is the correct hydraulic schematic for the PCU?

## Question 2

Q) Reference Scenario 9 - What will happen to lateral trim capability after the 12 degrees of lost motion is taken up?
A) Lateral trim capability will be limited to +/- 12 degrees of wheel. The force required to break out the transfer mechanism (50 Lb) is in excess of the feel and centering force ( $\sim 20 \mathrm{Lb}$ peak).

Question 3
What is the airplane level effect of lateral control scenario \#9 (spoiler control drum jammed at neutral)?
Boeing to run desktop simulation
Question 4
Provide proposed corrections to scenario \#10 write up
See rewrite.
Question 5
Q) Reference Scenario 9-10 - What is breakout force of the aileron spring cartridge?
A) Breakout force of the aileron spring cartridge (reflected at the control wheel) is approximately 16 Lb .

Question 6
Q) Reference Scenario 16 - What is the effect of a failure in the PCA input rod (A or B)?
A) There is no functional effect of a single failure in the PCA input rod. The entire input rod and fasteners are dual load path. The effect of a multiple failure depends on the position of the primary slide at the time of the failure. Worst case effect is a rate jam of the affected PCU, causing a force fight with the other PCU and stalling of both PCUs. Control of spoilers is available from the FO side if the transfer mechanism is broken out. Lateral trim will not be available. Depressurizing the affected PCU will restore normal control.

## Question 7

Q) Reference Scenario 17 - What is the effect of a jam between the primary and secondary slide in the aileron PCA?

1. If the primary slide and secondary slide jam together near neutral, the effect is a minor reduction in rate capability.
2. If the jam occurs away from neutral, the feedback motion of the PCU will cause the primary and secondary slides to counter each other (crossflow condition). At a full crossflow condition, the PCU will lose rate capability and be backdriven by the unaffected PCU.
Question 8
Q) Reference Scenario 18 - What is the effect of a jam between the secondary slide and the sleeve in the aileron PCA?
3. If the secondary slide jams near neutral, the effect is a minor reduction in rate capability.
4. If the jam occurs away from neutral, the feedback motion of the PCU will cause the primary and secondary slides to counter each other (crossflow condition). At a full crossflow condition, the PCU will lose rate capability and be backdriven by the unaffected PCU.

Question 9, 10
Q) Reference Scenarios 20, 21 - What is the effect of a piston to cylinder jam in the aileron PCA?
The effect is same as a jam elsewhere in the captain's side aileron control path. The FO must break out the transfer mechanism and aileron spring rod to move the spoilers. Aileron control is limited to deflections within the valve stops.

Question 11
Provide proposed corrections to scenario \#34 write up See rewrite.

Question 12
Provide proposed corrections to scenario \#36 write up See rewrite.

Question 13
Provide proposed corrections to scenario \#47 write up

## Flash Air Control Wheel Sensor Evaluation

## Introduction

- Define Sensor Malfunction
- Evaluate Data Quality

Validate Control Wheel Adjustments

## Discussion Points

Fact - Control Wheel Sensor Maximum Minimum Values Recorded on 25 -Hours of FDR data ( -2.237 deg to 81.5 deg) Theory - Control Wheel Sensor Moved Freely Within Active Range ( -2.237 and 81.5 degrees.), But due to Internal Binding of Rotating Components will not Exceed this Range.
Theory - Control Wheel Inputs Outside of Active Range Cause Sensor to Rotate in Mounting Bracket and Reposition Control Wheel Sensor/Cockpit Control Wheel Offset.
Theory - Rapid Control Wheel Inputs Will Also Cause Sensor to Shift in Mounting Bracket.
Theory - Control Wheel Sensor Values Can Be Used to Evaluate Crew Inputs When Sensor Offset can be Derived From Known Control Wheel Position (i.e. Before and After Preflight Control Checks, 0 - Aileron Deflection.)

## Discussion Points (cont.)

Control Wheel Position Sensor is a synchro with a range of 0 to 360 degrees or +- 180 degrees.
Full Range of Control Wheel as expressed in sensor units (synchro angles) is +- 128 degrees.
Full Range of Control Wheel Travel as measured in cockpit is +- 107 degrees.
The following discussion will reference sensor units only
(ie, synchro angles +- 128 degrees)
Theory - Control Wheel Position (Cockpit) values recorded during accident flight can be corrected to actual by applying the following offsets:

From Frame 92250 to 92361.92 subtract 17.5444 deg.
From Frame 92362.42 to 92445 subtract 28.9 deg.
From Frame 92446 to end of data 28.9 deg sensor offset may not apply due to rapid control wheel inputs.

## Control Wheel Position Sensor Values for Neutral Aileron Before \& After Prefilight Control Checks

|  | Time in Seconds <br> (FDR Sub Frame) | Control Wheel Position <br> Before Check <br> After Check |  | Control Check <br> Direction |

PROPRIOCEPTIVE ILLUSIONS
PREVENTION OF SPATIAL DISORIENTATION
TREATMENT OF SPATIAL DISORIENTATION

## Spatial Disorientation

Spatial disorientation contributes more to causing aircraft accidents than any other physiological problem in flight. Regardless of their flight-time experience, all aircrew members are subject to disorientation. The human body is structured to perceive changes in movement on land in relation to the surface of the earth. In an aircraft, the human sensory systems-the visual, vestibular, and proprioceptive systems-may give the brain erroneous orientation information. This information can cause sensory illusions, which may lead to spatial disorientation.

## COMMON TERMS OF SPATIAL DISORIENTATION

## SPATIAL DISORIENTION

9-1. Spatial disorientation is an individual's inability to determine his or her position, attitude, and motion relative to the surface of the earth or significant objects; for example, trees, poles, or buildings during hover. When it occurs, pilots are unable to see, believe, interpret, or prove the information derived from their flight instruments. Instead, they rely on the false information that their senses provide.

## SENSORY ILLUSION

$9-2$. A sensory illusion is a false perception of reality caused by the conflict of orientation information from one or more mechanisms of equilibrium. Sensory illusions are a major cause of spatial disorientation.

## VERTIGO

$9-3$. Vertigo is a spinning sensation usually caused by a peripheral vestibular abnormality in the middle ear. Aircrew members often misuse the term vertigo, applying it generically to all forms of spatial disorientation or dizziness.

## TYPES OF SPATIAL DISORIENTATION

## TYPE I (UNRECOGNIZED)

9-4. A disoriented aviator does not perceive any indication of spatial disorientation. In other words, he does not think anything is wrong. What he sees-or thinks he seesis corroborated by his other senses. Type I disorientation is the most dangerous type of disorientation. The pilot-unaware of a problem-fails to recognize or correct the disorientation, usually resulting in a fatal aircraft mishap:
-The pilot may see the instruments functioning properly. There is no suspicion of an instrument malfunction.
-There may be no indication of aircraft-control malfunction. The aircraft is performing normally.

- An example of this type of SD would be the height-/depth-perception illusion when the pilot descends into the ground or some obstacle above the ground because of a lack of situational awareness.

## TYPE II (RECOGNIZED)

9-5. In Type II spatial disorientation, the pilot perceives a problem (resulting from spatial disorientation). The pilot, however, may fail to recognize it as spatial disorientation:

- The pilot may feel that a control is malfunctioning.
-The pilot may perceive an instrument failure as in the graveyard spiral, a classic example of Type II disorientation. The pilot does not correct the aircraft roll, as indicated by the attitude indicator, because his vestibular indications of straight-and-level flight are so strong.

## TYPE III (INCAPACITATING)

9-6. In Type III spatial disorientation, the pilot experiences such an overwhelming sensation of movement that he or she cannot orient himself or herself by using visual cues or the aircraft instruments. Type III spatial disorientation is not fatal if the copilot can gain control of the aircraft.

## EQUILIBRIUM MAINTENANCE

9-7. Three sensory systems-the visual, vestibular, and proprioceptive systems-are especially important in maintaining equilibrium and balance. Figure $9-1$ shows these systems. Normally, the combined functioning of these senses maintains equilibrium and prevents spatial disorientation. During flight, the visual system is the most reliable. In the absence of the visual system, the vestibular and proprioceptive systems are unreliable in flight.

Figure 9-1. The Three Equilibrium Systems

## VISUAL SYSTEM

$9-8$. Of the three sensory systems, the visual system is the most important in maintaining equilibrium and orientation. To some extent, the eyes can help determine the speed and direction of flight by comparing the position of the aircraft relative to some fixed point of reference. Eighty percent of our orientation information comes from the visual system. (Chapter 8 contains information about the eye).

9-9. On flights under IMC, crew members lose fixed points of reference outside of the aircraft. Under IMC, the pilot must rely on visual sensory input from the instruments for spatial orientation. The decision to rely on the visual sense-and to believe the instruments rather than the input of the other senses-demands disciplined training.

9-10. The eyes allow the pilot to scan sensitive flight instruments that give accurate spatial-orientation information. These instruments indicate unusual aircraft attitudes resulting from turbulence, distraction, inattention, mechanical failure, or spatial disorientation.

## VESTIBULAR SYSTEM

9-11. The inner ear contains the vestibular system, which contains the motion- and gravity-detecting sense organs. This system is located in the temporal bone on each side of the head. Each vestibular apparatus consists of two distinct structures: the semicircular canals and the vestibule proper, which contain the otolith organs. Figure 9-2 depicts the vestibular system. Both the semicircular canals and the otolith organs sense changes in aircraft attitude. The semicircular canals of the inner ear sense changes in angular acceleration and deceleration.

Figure 9-2. The Vestibular System

## Otolith Organs

9-12. The otolith organs are small sacs located in the vestibule. Sensory hairs project from each macula into the otolithic membrane, an overlaying gelatinous membrane that contains chalklike crystals, called otoliths. The otolith organs, shown in Figure 93 , respond to gravity and linear accelerations/decelerations. Changes in the position of the head, relative to the gravitational force, cause the otolithic membrane to shift position on the macula. The sensory hairs bend, signaling a change in the head position.

Figure 9-3. The Otolith Organs
$9-13$. When the head is upright, a "resting" frequency of nerve impulses is generated by the hair cells. Figure 9-4 shows the position of the hair cells when the head is upright.

Figure 9-4. Position of the Hair Cells When the Head Is Upright
$9-14$. When the head is tilted, the "resting" frequency is altered. The brain is informed of the new position. The positions of the hair cells when the head is tilted forward and backward are shown in Figure 9-5.

Figure 9-5. Position of the Hair Cells When the Head Is Tilted Forward and Backward

9-15. Linear accelerations/decelerations also stimulate the otolith organs. The body cannot physically distinguish between the inertial forces resulting from linear accelerations and the force of gravity. A forward acceleration results in backward displacement of the otolithic membranes. When an adequate visual reference is not available, aircrew members may experience an illusion of backward tilt. Figure 9-6 shows this false sensation of backward tilt.

Figure 9-6. False Sensation During Backward Tilt

## SEMICIRCULAR CANALS

9-16. The semicircular canals of the inner ear sense changes in angular acceleration. The canals will react to any changes in roll, pitch, or yaw attitude. Figure 9-7 shows where these changes are registered in the semicircular canals.

Figure 9-7. Reaction of the Semicircular Canals to Changes in Angular Acceleration

9-17. The semicircular canals are situated in three planes, perpendicular to each other. They are filled with a fluid called endolymph. The inertial torque resulting from angular acceleration in the plane of the canal puts this fluid into motion. The motion of the fluid bends the cupula, a gelatinous structure located in the ampulla of the canal. This, in turn, moves the hairs of the hair cells situated beneath the cupula. This movement stimulates the vestibular nerve. These nerve impulses are then transmitted to the brain, where they are interpreted as rotation of the head. Figure 98 shows a cutaway section of the semicircular canal.

Figure 9-8. Cutaway View of the Semicircular Canals
9-18. When no acceleration takes place, the hair cells are upright. The body senses that no turn has occurred. The position of the hair cells and the actual sensation correspond, as shown in Figure 9-9.

Figure 9-9. Position of Hair Cells During No Acceleration
$9-19$. When a semicircular canal is put into motion during clockwise acceleration, the fluid within the semicircular canal lags behind the accelerated canal walls. This lag creates a relative counterclockwise movement of the fluid within the canal. The canal wall and the cupula move in the opposite direction from the motion of the fluid. The brain interprets the movement of the hairs to be a turn in the same direction as the canal wall. The body correctly senses that a clockwise turn is being made. Figure 910 shows the position of the hair cells and the resulting true sensation during a clockwise turn.

Figure 9-10. Sensation During a Clockwise Turn
9-20. If the clockwise turn then continues at a constant rate for several seconds or longer, the motion of the fluid in the canals catches up with the canal walls. The hairs are no longer bent, and the brain receives the false impression that turning has stopped. The position of the hair cells and the resulting false sensation during a
prolonged, constant clockwise turn is shown in Figure 9-11. A prolonged constant turn in either direction will result in the false sensation of no turn.

Figure 9-11. Sensation During a Prolonged Clockwise Turn
$9-21$. When the clockwise rotation of the aircraft slows or stops, the fluid in the canal moves briefly in a clockwise direction. This sends a signal to the brain that is falsely interpreted as body movement in the opposite direction. In an attempt to correct the falsely perceived counterclockwise turn, the pilot may turn the aircraft in the original clockwise direction. Figure $9-12$ shows the position of the hair cells-and the resulting false sensation when a clockwise turn is suddenly slowed or stopped.

Figure 9-12. Sensation During Slowing or Stopping of a Clockwise Turn

## PROPRIOCEPTIVE SYSTEM

9-22. This system reacts to the sensation resulting from pressures on joints, muscles, and skin and from slight changes in the position of internal organs. It is closely associated with the vestibular system and, to a lesser degree, the visual system. Forces act upon the seated pilot in flight. With training and experience, the pilot can easily distinguish the most distinct movements of the aircraft by the pressures of the aircraft seat against the body. The recognition of these movements has led to the term "seat-of-the-pants" flying.

## VISUAL ILLUSIONS

9-23. Illusions give false impressions or misconceptions of actual conditions; therefore, aircrew members must understand the type of illusions that can occur and the resulting disorientation. Although the visual system is the most reliable of the senses, some illusions can result from misinterpreting what is seen; what is perceived is not always accurate. Even with the references outside the cockpit and the display of instruments inside, aircrew members must be on guard to interpret information correctly.

## RELATIVE-MOTION ILLUSION

$9-24$. Relative motion is the falsely perceived self-motion in relation to the motion of another object. The most common example is when an individual in a car is stopped at a traffic light and another car pulls alongside. The individual that was stopped at the light perceives the forward motion of the second car as his own motion rearward. This results in the individual applying more pressure to the brakes unnecessarily. This illusion can be encountered during flight in situations such as formation flight, hover taxi, or hovering over water or tall grass.

## CONFUSION WITH GROUND LIGHTS

9-25. Confusion with ground lights occurs when an aviator mistakes ground lights for stars. This illusion prompts the aviator to place the aircraft in an unusual attitude to keep the misperceived ground lights above them. Isolated ground lights can appear as stars and this could lead to the illusion that the aircraft is in a nose high or one wing low attitude (Part A of Figure 9-13). When no stars are visible because of overcast conditions, unlighted areas of terrain can blend with the dark overcast to create the illusion that the unlighted terrain is part of the sky (Part B of Figure 9-13). This illusion can be avoided by referencing the flight instruments and establishing a true horizon and attitude.

Figure 9-13. Confusion of Ground Lights and Stars at Night

## FALSE HORIZON ILLUSION

The false horizon illusion (Figure 9-14) occurs when the aviator confuses cloud formations with the horizon or the ground. This illusion occurs when an aviator subconsciously chooses the only reference point available for orientation. A sloping cloud deck may be difficult to perceive as anything but horizontal if it extends for any great distance in the pilot's peripheral vision. An aviator may perceive the cloudbank below to be horizontal although it may not be horizontal to the ground; thus, the pilot may fly the aircraft in a banked attitude. This condition is often insidious and goes undetected until the aviator recognizes it and makes the transition to the instruments and corrects it. This illusion can also occur if an aviator looks outside after having given prolonged attention to a task inside the cockpit. The confusion may result in the aviator placing the aircraft parallel to the cloudbank.

Figure 9-14. False Horizon Illusion

## HEIGHT-DEPTH PERCEPTION ILLUSION

2-27. The height-depth perception illusion is due to a lack of sufficient visual cues and causes an aircrew member to lose depth perception. Flying over an area devoid of visual references-such as desert, snow, or water-will deprive the aircrew member of his perception of height. The aviator, misjudging the aircraft's true altitude, may fly the aircraft dangerously low in reference to the ground or other obstacles above the ground. Flight in an area where visibility is restricted by fog, smoke, or haze can produce the same illusion.

## CRATER ILLUSION

9-28. The crater illusion occurs when aircrew members land at night, under NVG conditions, and the IR searchlight is directed too far under the nose of the aircraft. This will cause the illusion of landing with up-sloping terrain in all directions. This misperceived up-sloping terrain will give the aviator the perception of landing into a crater. This illusionary depression lulls the pilot into continuing to lower the collective. This can result in the aircraft prematurely impacting the ground, causing damage to both aircraft and crew. If observing another aircraft during hover taxi, the aviator may perceive that the crater actually appears to move with the aircraft being observed.

## STRUCTURAL ILLUSIONS

9-29. Structural illusions are caused by the effects of heat waves, rain, snow, sleet, or other visual obscurants. A straight line may appear curved when it is viewed through the heat waves of the desert. A single wing-tip light may appear as a double light or in a different location when it is viewed during a rain shower. The curvature of the aircraft windscreen can also cause structural illusions, as illustrated in Figure 915. This illusion is due to the refraction of light rays as they pass through the windscreen. When encountering environments that contain these visual obscurants, the aviator must remain aware that these obscurants may present a false perception.

Figure 9-15. Structural Illusion

## SIZE-DISTANCE ILLUSION

9-30. The size-distance illusion (Figure 9-16) is the false perception of distance from an object or the ground, created when a crew member misinterprets an unfamiliar object's size to be the same as an object that he is accustomed to viewing. This illusion can occur if the visual cues, such as a runway or trees, are of a different size than expected. An aviator making an approach to a larger, wider runway may perceive that the aircraft is too low. Conversely, an aviator-making an approach to a smaller, narrower runway-may perceive that the aircraft is too high. A pilot making an approach 25 feet above the trees in the State of Washington, where the average tree is 100 feet tall, may fly the aircraft dangerously low if trying to make the same approach at Fort Rucker, Alabama, where the average tree height is 30 feet. This illusion may also occur when an individual is viewing the position lights of another aircraft at night. If the aircraft being observed suddenly flies into smoke or haze, the aircraft will appear to be farther away than before.

Figure 9-16. Size-Distance Illusion

## FASCINATION (FIXATION) IN FLYING

9-31. Fascination, or fixation, flying can be separated into two categories: task saturation and target fixation. Task saturation may occur during the accomplishment of simple tasks within the cockpit. Crew members may become so engrossed with a problem or task within the cockpit that they fail to properly scan outside the aircraft. Target fixation, commonly referred to as target hypnosis, occurs when an aircrew member ignores orientation cues and focuses his attention on his object or goal; for example, an attack pilot on a gunnery range becomes so intent on hitting the target that he forgets to fly the aircraft, resulting in the aircraft striking the ground, the target, or the shrapnel created by hitting the target.

## REVERSIBLE PERSPECTIVE ILLUSION

9-32. At night, an aircraft may appear to be moving away when it is actually approaching. If the pilot of each aircraft has the same assumption, and the rate of closure is significant, by the time each pilot realizes the misassumption, it may be too late to avoid a mishap. This illusion is termed reversible perspective and is often experienced when an aircrew member observes an aircraft flying a parallel course. In this situation, aircrew coordination is paramount. To determine the direction of flight, the aircrew member should observe the other aircraft's position lights. Remember the following: red on right returning; that is, if you see an aircraft with the red position light on the right and the green position light on the left, the observed aircraft is traveling in the opposite direction of your flight path.

## ALTERED PLANES OF REFERENCE

9-33. In altered planes of reference(Figure 9-17), the pilot has an inaccurate sense of altitude, attitude, or flight-path position in relation to an object so great in size that the object becomes the new plane of reference rather than the correct plane of reference, the horizon. A pilot approaching a line of mountains may feel the need to climb although the altitude of the aircraft is adequate. This is because the horizon, which helps the pilot maintain orientation, is subconsciously moved to the top of the ridgeline. Without an adequate horizon, the brain attempts to fix a new horizon.
Conversely, an aircraft entering a valley that contains a slowly increasing up-slope
condition may become trapped because the slope may quickly increase and exceed the ability of the aircraft to climb above the hill, causing the aircraft to crash into the surrounding hills.

Figure 9-17. Altered Planes of Reference

## AUTOKINESIS

9-34. Autokinesis primarily occurs at night when ambient visual cues are minimal and a small, dim light is seen against a dark background. After about 6 to 12 seconds of visually fixating on the light, one perceives movement at up to 20 degrees in any particular direction or in several directions in succession, although there is no actual displacement of the object. This illusion may allow an aviator to mistake the object fixated as another aircraft. In addition, a pilot flying at night may perceive a relatively stable lead aircraft to be moving erratically, when in fact, it is not. The unnecessary and undesirable control inputs that the pilot makes to compensate for the illusory movement of the aircraft represent increased work and wasted motion, at best, and an operational hazard at worst.

## FLICKER VERTIGO

9-35. Flicker vertigo (Figure 9-18) is technically not an illusion; however, as most people are aware from personal experience, viewing a flickering light can be both distracting and annoying. Flicker vertigo may be created by helicopter rotor blades or airplane propellers interrupting direct sunlight at a rate of 4 to 20 cycles per second. Flashing anticollision strobe lights, especially while the aircraft is in the clouds, can also produce this effect. One should also be aware that photic stimuli at certain frequencies could produce seizures in those rare individuals who are susceptible to flicker-induced epilepsy.

Figure 9-18. Flicker Vertigo

## VESTIBULAR ILLUSIONS

9-36. The vestibular system provides accurate information as long as an individual is on the ground. Once the individual is airborne, however, the system may function incorrectly and cause illusions. These illusions pose the greatest problem with spatial disorientation. Aircrew members must understand vestibular illusions and the conditions under which they occur. They must be able to distinguish between the inputs of the vestibular system that are accurate and those that cause illusion.

## SOMATOGYRAL ILLUSIONS

9-37. Somatogyral illusions are caused when angular accelerations and decelerations stimulate the semicircular canals. Those that may be encountered in flight are the leans, graveyard spin, and Coriolis illusions.

## Leans

$9-38$. The most common form of spatial disorientation is the leans. This illusion occurs when the pilot fails to perceive angular motion. During continuous straight-and-level flight, the pilot will correctly perceive that he is straight and level (part A, Figure 9-19). However, a pilot rolling into or out of a bank may experience perceptions that disagree with the reading on the attitude indicator. In a slow roll, for instance, the pilot may fail to perceive that the aircraft is no longer vertical. He may feel that his aircraft is still flying straight and level although the attitude indicator shows that the aircraft is in a bank (part B, Figure 9-19). Once the pilot detects the slow roll, he makes a quick recovery. He rolls out of the bank and resumes straight-and-level flight. The pilot may now perceive that the aircraft is banking in the opposite direction. However, the attitude indicator shows the aircraft flying straight and level (part C, Figure 9-19). The pilot may then feel the need to turn the aircraft so that it aligns with the falsely perceived vertical position. Instead, the pilot should maintain straight-and-level flight as shown by the attitude indicator. To counter the falsely perceived vertical position, the pilot will lean his body in the original direction of the subthreshold roll until the false sensation leaves (part D, Figure 9-19).

Figure 9-19. Leans

## Graveyard Spin

9-39. This illusion, shown in Figure 9-20, usually occurs in fixed-wing aircraft. For example, a pilot enters a spin and remains in it for several seconds. The pilot's semicircular canals reach equilibrium; no motion is perceived. Upon recovering from the spin, the pilot undergoes deceleration, which is sensed by the semicircular canals. The pilot has a strong sensation of being in a spin in the opposite direction even if the flight instruments contradict that perception. If deprived of external visual references, the pilot may disregard the instrumentation and make control corrections against the falsely perceived spin. The aircraft will then reenter a spin in the original direction.

Figure 9-20. Graveyard Spin
9-40. To compound the action of the semicircular canals under these conditions, a pilot, noting a loss of altitude as the spin develops, may apply back pressure on the controls and add power in an attempt to gain altitude. This maneuver tightens the spin and may cause the pilot to lose control of the aircraft.

## Coriolis Illusion

9-41. Regardless of the type of aircraft flown, the Coriolis illusion is the most dangerous of all vestibular illusions. It causes overwhelming disorientation.

9-42. This illusion occurs whenever a prolonged turn is initiated and the pilot makes a head motion in a different geometrical plane. When a pilot enters a turn and then remains in the turn, the semicircular canal corresponding to the yaw axis is equalized. The endolymph fluid no longer deviates, or bends, the cupula. Figure 9-21 shows the movement of the fluid in a semicircular canal when a pilot enters a turn.

Figure 9-21. Movement of Fluid in the Semicircular Canals During a Turn
9-43. If the pilot initiates a head movement in a geometrical plane other than that of the turn, the yaw axis semicircular canal is moved from the plane of rotation to a new plane of nonrotation. The fluid then slows in that canal, resulting in a sensation of a turn in the direction opposite that of the original turn.

9-44. Simultaneously, the two other canals are brought within a plane of rotation. The fluid stimulates the two other cupulas. The combined effect of the coupler deflection in all three canals creates the new perception of motion in three different planes of rotation: yaw, pitch, and roll. The pilot experiences an overwhelming head-over-heels tumbling sensation.

## SOMATOGRAVIC ILLUSIONS

9-45. Somatogravic illusions are caused by changes in linear accelerations and decelerations or gravity that stimulate the otolith organs. The three types of somatogravic illusions that can be encountered in flight are oculogravic, elevator, and oculoagravic.

## Oculogravic Illusion

9-46. This type of illusion occurs when an aircraft accelerates and decelerates. Inertia from linear accelerations and decelerations cause the otolith organ to sense a nose-high or nose-low attitude. In a linear acceleration, the gelatinous layer, which contains the otolith organ, is shifted aft. The aviator falsely perceives that the aircraft is in a nose-high attitude. A pilot correcting for this illusion without cross-checking the instruments would most likely dive the aircraft. This illusion does not occur if adequate outside references are available. If making an instrument approach in inclement weather or in darkness, the pilot would be considerably more susceptible to the oculogravic illusion. An intuitive reaction to the sensed nose-high attitude could have catastrophic results

## Elevator Illusion

9-47. This illusion occurs during upward acceleration. Because of the inertia encountered, the pilot's eyes will track downward as his body tries, through inputs
supplied by the inner ear, to maintain visual fixation on the environment or instrument panel. With the eyes downward, the pilot will sense that the nose of the aircraft is rising. This illusion is common for aviators flying aircraft that encounter updrafts.

## Oculoagravic Illusion

$9-48$. This illusion is the opposite of the elevator illusion and results from the downward movement of the aircraft. Because of the inertia encountered, the pilot's eyes will track upward. The pilot's senses then usually indicate that the aircraft is in a nose-low attitude. This illusion is commonly encountered as a helicopter enters autorotation. The pilot's usual intuitive response is to add aft cyclic, which decreases airspeed below the desired level.

## PROPRIOCEPTIVE ILLUSIONS

9-49. Proprioceptive illusions rarely occur alone. They are closely associated with the vestibular system and, to a lesser degree, with the visual system. The proprioceptive information input to the brain may also lead to a false perception of true vertical. During turns, banks, climbs, and descending maneuvers, proprioceptive information is fed into the central nervous system. A properly executed turn vectors gravity and centrifugal force through the vertical axis of the aircraft. Without visual reference, the body only senses being pressed firmly into the seat. Because this sensation is normally associated with climbs, the pilot may falsely interpret it as such. Recovering from turns lightens pressure on the seat and creates an illusion of descending. This false perception of descent may cause the pilot to pull back on the stick, which would reduce airspeed. Figure 9-22 shows proprioceptive illusions.

Figure 9-22. Proprioceptive Illusions

## PREVENTION OF SPATIAL DISORIENTATION

9-50. Spatial disorientation cannot be totally eliminated. However, aircrew members need to remember that misleading sensations from sensory systems are predictable. These sensations can happen to anyone because they are due to the normal functions and limitations of the senses. Training, instrument proficiency, good health, and aircraft design minimize spatial disorientation. Spatial disorientation becomes
dangerous when pilots become incapable of making their instruments read right. All pilots, regardless of experience level, can experience spatial disorientation. For that reason, they should be aware of the potential hazards, understand their significance, and learn to overcome them. To prevent disorientation, aviators should-

- Never fly without visual reference points (either the actual horizon or the artificial horizon provided by the instruments).
-Trust the instruments.
-Avoid fatigue, smoking, hypoglycemia, hypoxia, and anxiety, which all heighten illusions.
- Never try to fly VMC and IMC at the same time.

## TREATMENT OF SPATIAL DISORIENTATION

9-51. Spatial disorientation can easily occur in the aviation environment. If disorientation occurs, aviators should-

- Refer to the instruments and develop a good cross-check.
-Delay intuitive actions long enough to check both visual references and instruments.
- Transfer control to the other pilot if two pilots are in the aircraft. Rarely will both experience disorientation at the same time.

### 1.17. Organizational and Management Information

### 1.17.1. Flash Airlines

1.17.1.1. Flash Airlines Air Operator Certificate (AOC)

Flash Airlines was approved as air operator (charter air carrier) under ECAR 121 by the ECAA, and operating under approval no 018.

Flash Airlines has its main office in Cairo, Egypt at 166b El Hegaz St. Heliopolis. Beginning in 2000, Flash Airlines leased the first B737-300 from the International Lease Financial Corporation (ILFC). In June 2001 another B737-300 from ILFC was added to Flash Airlines fleet, which made the company fleet two aircraft the same type. The Operations Specifications was issued to the company in Feb 2000 and the last revision was on October $29^{\text {th }}$ 2003.

# AIR OPERATOR CERTIFICATE 

This certifies that

## FLASH AIRLINES

Has met the requirements of the MINISTRY OF CIVIL AVIATION and related operating regulations and rules prescribed thereunder for the issuance of this certificate and is hereby authorized to conduct Air-Carrier operation in accordance with said operating regulations and rules prescribed thereunder and the terms, conditions and limitations contained in the . attached Operation Specifications.

This certificate is not transferable and, unless sooner surrendered, suspended or revoked, shall continue in effect until February 23, 2004 or terminated.

Pilot / Saleh Moussa saleh.A. Mous
Head of Operations \& Air Transpor (4) etotints

CERTIFICATE NO.: 18
CERTIFICATE ISSUE DATE : February 24, 2000

### 1.17.1.2. History

Flash Airlines is also approved under ECAR 145 as a repair station. The approval number is CAI/FLASH?AS/1/2001. The certificate is valid until July $30^{\text {th }}, 2004$ and was issued on July 31, 2001. The certificate is limited to line maintenance up to the 8A check for the B737-300. Flash Airlines maintenance base is Cairo international Airport.

Flash Airline Organization Chart:

Figure 1.17.1-1 Flash Airlines Organization Chart

Flash Airlines coordinates the maintenance program through its ECAR Part 145 certificate. The Company General Maintenance Manual (GMM) provides guidance related to the Aircraft Maintenance program as the Maintenance Procedures, Maintenance staff Training... etc.

Personnel working on Flash Airlines Fleet at the various maintenance facilities must be familiar with the policies and procedures spelled out in the company GMM. The Quality Control Manager puts the newly hired employees through a twelve-hour Indoctrination Course. The Indoctrination course includes Flash Airlines policy/ procedures, and training practices. It is accomplished before maintenance engineer begins to work at the Flash Airlines facility. The training is documented on a maintenance training attendance record, recorded on the employee's training file.
1.17.1.3. Personnels Training and Authorization
1.17.1.3.1. Maintenance Engineers

According to ECAR 65 the requirements for granting authorization for ground engineer are as follow:
1- $\quad$ Graduation from Faculty of Engineering or an approved training institute.
2- $\quad$ Passing the approved Basic training Course at approved Training Center or institute.
3- $\quad$ On Job Training for 18 months.
4- Passing written, practical and oral exams by the authority for License without Type Rating (LWTR).
5- $\quad$ Passing an approved training course for a specific type airframe and engine.
6- $\quad$ On Job Training (OJT) on the type airframe and engine for 9 months.
7- Attendance of training course for the company exposition procedure manual.
8- Passing oral and practical examination in front of the Company
Examination Board (approved by the authority)
$9-\quad$ Getting the company approval.
Flash Airlines maintains its training program in compliance with Egyptian Civil Aviation Regulation requirements. The Maintenance Director and the Quality Control Manager have joint responsibility for assuring all required training is performed and recorded.

Indoctrination training proceeds an employee's start date. The employee is given a 4-hour introduction course that trains one on Flash Airlines maintenance policies and procedures. The training will be documented on a maintenance training attendance record and maintained in the employee's training file.

The aircraft systems training for the A \& C Engineers is accomplished through formal systems training and On-the-Job Training (OJT) Worksheets.

Engineer Mustafa Erfan carried out the last pre- flight release.

### 1.17.1.3.2. Cockpit Crews

Refer to Exhibit F Operation Group Factual Report, Attachment 1

### 1.17.2. Review of oversight by ECAA on 2003

1.17.2.1 Safety oversight carried out on Flash Airline during the period from 2 Jan, 2003 to 16 Jan 2003 before AOC renewal
The oversight findings and the relevant actions taken by the airline are shown in the table below

A- Operation Findings

|  | Findings | Actions Taken |
| :---: | :--- | :--- |
| 1 | There is no Training Program | Training Program is submitted and <br> approved |
| 2 | There is no Internal Evaluation <br> Program (IEP) | IEP is submitted and approved |
| 3 | There is no Line check Training for <br> Captains | Line Check Training is performed |
| 4 | No ECAR Training Course was <br> performed recently | Training course has started and it will <br> take some time to cover all the operation <br> personnel |
| 5 | There is no approved Training Class | Training Class is Approved. |
| 6 | There are no DRM \&CRM Training <br> course performed for cockpit crews <br> ,dispatchers and cabin crews | The Airline has introduced a training <br> plan starting on Sep 2003 to be done in <br> PAS Airline |
| 7 | No of cockpit crews are not fulfilling the <br> minimum requirement of ECAA | The cockpit crews are sufficient for <br> required operation and the airline will <br> recruit more cockpit crews to fulfill the <br> future operation requirements |
| 8 | By reviewing the A/C log book sheets <br> found that ,some sheets not filled out <br> and other some have missed data | The airline issued circular for all cockpit <br> crews and maintenance staff to strictly <br> comply with log book sheets filling out <br> instructions |
| 9 | By reviewing the airline TM,GOM and <br> Dispatch Manual some findings were <br> discovered | All findings are covered <br> 10The submitted station manual not <br> fulfilling ECAA requirements |
| 11 | The Safety Manual which was <br> submitted by the airline does not meet <br> ECAA requirements | The Station Manual was updated to fulfill <br> the ECAA requirements |
| 12 | Nabin Crew does not use safety and <br> emergency check lists | A circular was issued for the cabin crew <br> to strictly comply with the written <br> instruction for using the check lists |
| 13 | There is no security program for <br> Aircraft | The program is submitted and approved <br> 14Load sheet calculations for some <br> flights not accurate |
| Load sheet calculations training course <br> is planned to be done for all flight <br> dispatchers |  |  |

B-Airworthiness Findings

|  | Findings | Actions Taken |
| :---: | :--- | :--- |
| 1 | There is shortage of some <br> maintenance equipment and tools | The unavailable equipment and tools will <br> be loaned from EgyptAir when required |
| 2 | Personnel files are not updated | Files are updated |
| 3 | GMM is not Updated | GMM is updated |
| 4 | There is no AMM in the library | AMM is Available now in the library |
| 5 | MPD, AFM, CMEL, and FOM are not <br> Updated | All manuals are updated |
| 6 | There is no Training Program for <br> Recurrent Course | The recurrent training program was <br> submitted and approved |
| 7 | Authorization Board does not include <br> electric engineer | The electric engineer authorization will <br> be issued by ECAA |
| 8 | The airline has not submitted SOC 121 | SOC 121 was submitted and Accepted |
| 9 | Some parts are not calibrated | The parts required to be calibrated were <br> sent to EgyptAir for calibration |
| 10 | Safety wire of fire bottles do not meet <br> the standards | Safety wire corrected to meet the <br> standards |
| 11 | Spare parts in the store are not <br> sufficient | The required spare parts will be loaned <br> from EgyptAir when required |
| 12 | A/C tires storage is not according to the <br> storage requirement | Storage requirement familiarization <br> course is performed for the storage <br> keepers |
| 13 | The storage keepers are not familiar <br> With GMM | GMM training course is planned to be <br> performed |
| 14 | There is no safety requirement <br> program | The program is submitted and approved <br> 15By reviewing the TLB Sheets ,found <br> that , some sheets not including PDC <br> Maintenance Release and ECM data |
| An inspection Circular is issued for the <br> maintenance personnel sign PDC <br> Release after PDC performing |  |  |

1.17.2.2 Safety oversight carried out on Flash Airline on 16 Jul 2003 before AMO Certificate renewal
The oversight findings and the relevant actions taken by the airline are shown in the table below

|  | Findings | Action Taken |
| :--- | :--- | :--- |
| 1 | There is no W\&B Program | The program is submitted and approved |
| 2 | Human factors training program for <br> the engineers not yet submitted to <br> ECAA for approval | Human factors training program for <br> engineers is submitted to ECAA and <br> approved |

1.17.3. Relevant Flash Airlines procedures:
1.17.3.1 Flash Airlines procedures regarding use of autopilot when recovering from unusual attitudes
Refer to Flash Airline FOM (Ops Group)
1.17.3.2 Flash Airlines procedures regarding Upset Recovery training

MCA requirements regarding Upset Recovery are not mandatory.
Refer to Flash Airline FOM (Ops Group)
1.17.3.3 Flash Airlines procedures regarding "training about PNF assuming control when the PF is not responding to situations, callouts"

| FLASHAIR | CHAPTER 4 |
| :--- | :--- |
| CREW HEALTH PRECAUTIONS |  |

.............................
crew member incapacitation.
This includes avoidance of drugs, moderate consumption of alcohol, adequate rest time -and its proper use for recreation adequate sleep and nutrition but
mere is ant mustration ot the use of the Two Communication Rule:

1. the PNF, for example, notices the airplane is left of course,

| (7) FLASHAIR | CHAPTER 4 | FSH - 4.1.4 |
| :--- | :---: | :---: |
|  | CREW HEALTH PRECAUTIONS |  |

that position you initially were assigned to

- organise work after landing; this shall include
- depending on the situation, a change of seats for taxiing in, but only after the aeroplane has come to a complete stop;
- having the incapacitated crew member offloaded and to the ambulance as quickly as possible;
- arrangements for the parking of the aeroplane.

## NOTE:

1. The company operations department must be kept informed at all times regarding the above circumstances for immediate relay to the Manager Flight Operations.
2. In case of incapacitation of the system panel operator, pilots shall refer to procedures as published in the AOM.

### 4.1.7 Summary

The problems involved with incapacitation of crew members may be summarised as follows:

1) If you do not feel well, say "NO" before the flight.
2) Remember, that the best medical examination as well as a health conscious life still do not guarantee that an incapacitation during flight will not happen to you or to your other crew members.
3) The "TWO

COMMUNICATION RULE"
must be used in order to have a chance of detecting any incapacitation in time. Take notice of any abnormal or unusual action of another crew member, as this might also be an indication of onset of incapacitation.
4. Once an incapacitation is identified, remember the three basic steps:
Step 1) Take over the aeroplane and bring it under YOUR control.
Step 2) Take care of the incapacitated pilot (either have him removed from his seat or fixed so that he will not interfere the controls).
Step 3) Prepare for landing.
Finally, it is emphasised that incapacitation requires special actions using the good judgement of the crew member left in command of the aeroplane.

### 4.2 ALCOHOLIC

 BERVERAGESThe use of intoxicating beverages by FLASH AIR flight crew members must of necessity be strictly regulated.
The following rules must be strictly observed by all flight crew members at all times:

1. No alcoholic beverage shall be consumed on the same calendar day that a crew

30 Jan 03
Flight Operations Manual
1.17.3.4 Flash Airlines training/operational information regarding intervention by the non-flying pilot when the flying pilot fails to respond to calls for correcting an unsafe situation. Refer to previous item
1.17.3.5 Regularity (or irregularity) rules regarding sleeping schedules on and off-duty. Strategies for obtaining adequate rest and managing crew on-duty alertness Refer to Flash Airline FOM (Ops Group)
1.17.3.6 General description about Flash Airline. (Date of foundation or transition, location of offices and bases, number of aircrafts operated, number of pilots and other personnel, annual flights, passengers carried, revenues, routes flown, and financial health) (All relevant information are already included in the Factual Report)
1.17.3.7 Labor management issues, growth trends, and main competitors.
Closed
1.17.3.8 Egyptian requirements for the training of pilots at an airline such as Flash Airlines.

GENERAL. The following outline is intended to clarify the six categories of training used by operators and defined in Part 121 , Subpart N. This clarification is intended to both define the type of training and describe for the Operator when each category of training is applicable.

APPLICABILITY OF TRAINING CATEGORIES. Usually, operators will need to conduct training in all six categories of training. Recurrent training applies to all operators. Initial equipment training, transition training, upgrade training, and requalification training apply in most situations. However, transition training is not applicable for an operator who operates only one aircraft type. Initial new hire training applies to operators who train and qualify newly hired personnel or personnel who have not been previously qualified as a crewmember by that operator.

CATEGORIES OF TRAINING. There are six basic categories of training applicable to Part 121 operators. The primary factors which determine the appropriate category of training are the student's previous experience with the operator and previous duty position. Each category of training consists of one or more curriculums, each one of which is specific to an aircraft type and a duty position (for example: A-320 SIC, and A-320 PIC). Training should be identified with and organized according to specific categories of training. When discussing training requirements, MoCA inspectors should be specific regarding the category of training being discussed and use the same references as are stated in Part 121 Subpart N. Inspectors should encourage operators to use this nomenclature when developing new training curriculums or revising existing training curriculums. Use of this common nomenclature improves standardization and mutual understanding. The six categories of training are briefly discussed in the following subparagraphs:
A. Initial New Hire Training. This training category is for personnel who have not had previous experience with the operator (newly hired personnel). It also applies, however, to personnel employed by the operator who have not previously held a cockpit crewmember duty position with that operator. Initial new hire training includes basic indoctrination training and training for a specific duty position and aircraft type. Except for a basic indoctrination curriculum segment, the regulatory requirements for "initial new hire" and "initial equipment" training are the same. Since initial new hire training is usually the employee's first exposure to specific company methods, systems, and procedures, it must be the most comprehensive of the six categories of training. For this reason, initial new hire training is a distinct separate category of training and should not be confused with initial equipment training. Initial equipment training is a separate category of training.
B. Initial Equipment Training (PIC and SIC). This category of training is for personnel who have been previously trained and qualified for a duty position by the operator (not new hires) and who are being reassigned for any of the following reasons:
(a) Reassignment is to any duty position on an airplane of a different group (Group IIIP is reciprocating and turbopropeller powered and Group IIIJ is turbojet powered).
(b) Reassignment is to a different duty position on a different airplane type when the cockpit crewmember has not been previously trained and qualified by the operator for that duty position and airplane type.
C. Transition Training. This category of training is for an employee who has been previously trained and qualified for a specific duty position by the operator and who is being assigned to the same duty position on a different aircraft type and the different type aircraft must be in the same group. If it is not in the same group, initial equipment training is the applicable category of training.
D. Upgrade Training. This category of training is for an employee who has been previously trained and qualified as SIC or PIC (not eligible for requalification training) by the operator and is being assigned as PIC to the same aircraft type for which the employee was previously trained and qualified as SIC or PIC on the same type.
E. Recurrent Training. This category of training is for an employee who has been trained and qualified by the operator, who will continue to serve in the same duty position and aircraft type, and who must receive recurring training and/or checking within an appropriate eligibility period to maintain currency.
F. Requalification Training. This category of training is for an employee who has been trained and qualified by the operator, but has become unqualified to serve in a particular duty position and/or aircraft due to not having received recurrent training and/or a required flight or competency check within the appropriate eligibility period. Requalification training is also applicable in the following situations:

* PICs who are being reassigned as SICs on the same aircraft type when seat dependent training is required
* PICs and SICs who are being reassigned as FEs on the same aircraft type, provided they were previously qualified as FEs on that aircraft type
G. Summary of Categories of Training. The categories of training are summarized in general terms as follows:
(a) All personnel not previously employed by the operator must complete initial new hire training.

| Issue 2, Rev. 0 | Dated July, 2002 Page 1 |
| :--- | :--- | :--- |

## Ministry of Civil Aviation

Training Standards Handbook
(b) All personnel must complete recurrent training for the duty position and aircraft type for which they are currently assigned within the appropriate eligibility period.
(c) All personnel who have become unqualified for a duty position on an aircraft type with the operator must complete requalification training to reestablish qualification for that duty position and aircraft type.
(d) All personnel who are being assigned by the operator to a different duty position and/or aircraft type must complete either initial equipment, transition, upgrade, or requalification training depending on the aircraft type and duty position for which they were previously qualified.

1.17.3.10 Flash Airlines procedures regarding pilots training and checking on operation of the auto flight system. . No specific form is available (refer to 1.5.1 and 1.5.2)
1.17.3.11 Flash Airlines program for training and checking pilots in the field of CRM and human factors (as contained in the company training manual)
No mandatory training was required by ECAR at the time of the accident. However, CRM course is outlined in Flash Airline Training Manual 4.10
1.17.3.12 Flash Airlines pilots procedures for training and checking pilots on spatial disorientation countermeasures and upset recovery
Spatial Disorientation training is not a requirement by Civil Aviation Authorities. However, some literature about this subject is included in Flash Airline Training Manual.
1.17.3.13 Flash Airlines policies regarding use of CRM. Refer to 1.17.3.11.
1.17.3.14 Flash Airlines policies relating to assertiveness and company guidelines as to when a first officer should take control of an aircraft from a captain. Refer to 1.17.3.3.
1.17.3.15 Flash Air general company policies related to crew communication, assertiveness, and other CRM-related behaviors
Refer to 1.17.3.3.
1.17.3.16 Flash Airlines policies regarding use of the auto flight system (To be referred to the OPS group)
1.17.3.17 Regulations governing operators (like Flash Airlines) regarding Oversight audits by ECAA. ECAA regulations require every operator to undergo an oversight audit once every 12 month
1.17.3.18 Details about the ECAA oversight audit on Flash Airlines Is already included in the Factual Report
1.17.3.19 Outcomes of Oversight audits (previous violations, fines, or bans levied by ECAA) Is already included in the Factual Report
1.17.3.20 Previous violations, fines, or bans levied foreign aviation regulatory agencies.
None identified
Reviewing this report indicated that the ban was due to a conflict on financial issues and no relevant safety issues were mentioned.
1.17.3.21 Selected additional information regarding Flash Airlines Organization including:

- Organization and responsibilities Chapter 1 FSH 1.5.1/ 1.5.2
- Organization and responsibilities Chapter 1 FSH 1.8.7
- Qualification requirements Chapter 3 FSH 3.3.1/ 3.3.2
- Crew Health Precautions Chapter 4 FSH-4.1.1- 4.1.4
- Operating Procedures Chapter 6 FSH 6.3.44/ 6.3.45/ 6.3.46
- Training details Flash Training Manual Chapt 05 Page 7

All pertinent information are included in the Factual Report
1.17.3.22 Airline Simulator program contract with RAM, ECAA letter of approval

1.17.3.23 Simulator used by Flash Airlines at RAM).

Including

- FCC options
- Ground proximity
- Bank angle options
- Display type installed
- FD type (split or integrated cue)

See section 1.16.1.10.
1.17.3.24 Flash Airlines procedures regarding which pilot (PF or PNF) engages the autopilot, Boeing recommended practice No written procedure was found in Flash Airline FOM regarding this issue. Boeing procedures and common practices are for PF to connect the autopilot.
1.17.3.25 Additional information regarding dispatch from SSH
A. All departures from SSH (accident aircraft)

-7 Departure from SSH
-9 Departure from SSH
-11 Departure from SSH
-13 Departure from SSH
Same crew did flight no13 "Accident flight" and flight no 9 "SSH /TRN", following a comparison between the two flights.

B- Extension of the outbound legs before beginning the turn
Interviewing Flash Airlines chief pilot: Flash Airlines chief pilot stated that during the departure from SSH, Flash Airline pilots might extend the circuit as the situations need whether day or night departures (departure over water is mandatory)

Actual pattern flown depends on airplane performance (weight, OAT, etc). Most airplanes widen the pattern to gain additional altitude as a pilot technique. VOR crossing altitude restriction is shown on charts. This information should be added to Operations Group Notes.

### 1.18. Additional Information

## Flash Airlines Flight 604 Investigation Crew Behavior Subcommittee

## Minutes of a Meeting Held at the Offices of the Ministry of Civil Aviation

## Cairo, Egypt

August 23-26, 2004

## Materials Provided by MCA

1. Paragraph interview summaries
2. One page summary of medical records provided to MCA by Egyptian Air Force after the retirement of the accident captain
3. Ops group chairman's factual report
4. Capt's flight time summary \& schedule for previous 30 days
5. FO's flight time summary \& schedule for previous 30 days
6. Capt's MCA pilot certification file
7. Capt's CV (1-page summary of qualifications and type certificates)
8. Captain's meteorology training course certificate from Egyptian Air Force (taken by Capt in 1984 and provided to MCA when he became civil pilot)
9. Capt's Proficiency Check Form from May 12, 2003 and transition training form from May 13, 2003
10. Capt's recurrent training form from Dec 16, 2003
11. Capt's Line Check form from July 23, 2003
12. Capt's Oral Exam form from May 12, 2003
13. Capt's ICE training form from May 28, 2003
14. Capt's Fixed Base Sim training record from April 28, 2003
15. Capt's Full Flight Sim training record from May 3-12, 2003
16. Capt's flight time records from the Air Force, Dec 14, 1999
17. FO's MCA pilot certification file
18. FO's transition training record from June, 2002
19. Flash Air Ground syllabus for $737-300$ course
20. FO's Proficiency Check Form from June 30, 2002
21. page \#2 of previous
22. FO's Proficiency Check Form from July 11,2002 (difficult to read)
23. FO's ICE training form from Aug 12, 2002
24. page \#2 and \#3 of previous
25. FO's Competency Check (ground school on emergency operations- training conducted at Egypt Air) from May 22, 2002
26. FO's Proficiency Check form from May 15-16, 2003
27. FO's Recurrent Training form from Dec 11, 2003
28. FO's Flash Air special course on emergency procedures, HAZMA T, first aid (practical test tied to handling dangerous goods)
29. FO's MCA test performance and systems certification oral exam
30. FO's basic indoctrination course form (from MCA at Egypt Air facility)
31. FO's ICE form

32-39 -FO's full flight simulator training form from June 22-July 7, 2002
40. MCA CVR-FDR overlay plots (3 pages)

Materials made available for review during the meeting:

- MCA medical certification records of the captain
- Flash Air general operations manual
- Flash Air training manual

## Definition of spatial disorientation

Spatial disorientation is an incorrect perception of attitude, altitude or motion of one's own aircraft relative to the position of the Earth.

Type I spatial disorientation:
Unrecognized spatial disorientation. No conscious perception of SD.
Distractions are often antecedents to the accident. Crash with no distress or concern expressed. No mayday or other than routine communications. Unusual or inappropriate aircraft attitude, but pilot does not make any appropriate corrective action. Pilot is apparently oblivious to the situation.

Type II recognized:
Conscious manifestation of a problem. Pilots often incorrectly refer to this experience as vertigo. Pilot recognizes conflict between perceived and intended or expected attitude. Can assume that the instruments are operating incorrectly. Might not properly react because of difficulty accepting indicated correct control input or might just be puzzled about the situation. Confusion might persist after recovery and lead to compounding of SD problem.
\{Veronneau, S.J.H. \& Evans, R.. (2004). Spatial disorientation mishap classification, data and investigation. Previc, F.H. \& Ercoline, W.R. (Eds) Spatial disorientation in aviation. American institute of Aeronautics and Astronautics.\}

## Conditions for establishing spatial disorientation

1. Presence of inaccurate or misleading vestibular cues.
2. Absence of visual cues or presence of misleading visual cues.
3. Presence of a distraction capable of drawing attention away from attitude displays.

## Closing Comments

This is a preliminary report. More work is needed to comprehensively address all human factors issues relevant to this accident, as needed.
Complete minutes of CBS meeting will be made available to the sub committee for further work and analysis

- A.V.M. Ibrahim Omran,

Worked together in the Egyptian Air Force and later in Civil Aviation.
A religious man, accurate in his work, does not recall medical complaints or use of any significant medication, was aware of maintaining his health, had self respect in all dealing with others.

- MRS. Olfat - wife of Captain Kheider

Spoke very highly of him; he never created any problem for her all through their married life - chose to cure any minor health problem by using natural components such as herbs - played soccer until five years ago never complained of headaches, dizziness or unbalance, did not mention any work related problems to her or his children.

- Meeting with Captain Khedr's wife 24/10/2004

All his life Captain Khedr motivation for flight was very high he used to care of his health and eat organic foods and much salad. When he is expecting a journey he used to close his room to have a good sleep while taking off the telephone. He was married since 30 years; he has 3 children and one grand child. Two children are living with him.

No accidents either aeroplane or crush car was reported. He was much praised at work. In the year 1997 he was awarded a prize when he landed in a difficult weather in Sarayevo.

- First Officer Yasser Elseesy Important note: F/O Elseesy flew with Captain Kheider 48 hours prior to the crash.
Had good relations with everybody regardless of position or rank. The last flight was the F/O birthday and the Captain celebrated the event on the A/C by sharing a cake with all the crew, this gesture left a very positive impression on everybody.
- First Officer Hany El Meligy

Says Captain Kheider was calm and balanced person and in spite of his long experience he always took time to read and prepare well before any flight, he was well disciplined and did not smoke.

- First Officer Sherif Darwish

Flew frequently with Captain Kheider, learnt a lot from him and his long experience, was of good character, calm during flights and he did not observe anything about his behavior that was not normal.

- First Officer Heba Darwish

Flew frequently with Captain Kheider, she says that he was intelligent, observant and highly concentrated on his work during flights, balanced, calm and disciplined.

- Meeting with traffic officer Mr. Amr Shawky (Sharm El Sheikh Station Manager)

Mr. Amr met the 3 crew members and he know them well during the months proceeding the accident. Crew members:

1) Captain Khedr.
2) F/O Amr El Shafy.
3) Engineer Mostafa Askar.

He used to see them in the office during work and a lot during rest periods in Sharm El Sheikh City. Either staying in a hotel or taking supper together in a restaurant in the City.
He noticed they were pleasant and within normal behavior. No special incidents or accidents or quarries occurred during that period.
Captain Khedr was specially accurate and meticulous in his work and famous for his punctuality. He likes his work very much and talks about it with pride and satisfaction. He used to smile and talk nicely to all crew members specially before flights. Between journeys he used to stay at hotel taking complete rest. I used to see Captain Khedr daily in between trips.
On the $3^{\text {rd }}$ day before accident nothing specially was observed with normal relationship with a crew.

## - On the day of the accident

Due to pressures of reservation in hotels, Captain Khedr and F/O were in Fantasia hotel and the rest of the crew was in Coral Beach Hotel. The bus brought the crew first then the Captain and first officer from the $2^{\text {nd }}$ hotel with a difference of 15 min . the aeroplane arrived and I gave them the documents and Captain Khedr requested the usual questions (like the № of passengers).

Captain Khedr was joking with me and told me I can take you with me now to Cairo (on aeroplane) this happened while the first officer is busy checking, the different systems of aeroplane and entering the computerized route plan he is usual a calm person with little but pleasant talking.

### 1.19. New Investigation Techniques

1.19.1 Spatial disorientation:

- Definition
- The way the SD works
- Crew fatigue
- Human related factors

Refer to (tests and researches), 1.16.4. Tests and researches conducted by MCA, Spatial Disorientation Studies
Additional work can be done through adding the report of the CBS group meeting)

Exhibits

## Exhibit A

## AIRCRAFT MAINTENANCE RECORDS GROUP FACTUAL REPORT

Ministry of Civil Aviation
Accident Investigation Central Administration
Accident Investigation Team
Cairo, January 26,2004

# AIRCRAFT MAINTENANCE RECORDS GROUP <br> FACTUAL REPORT 

## A. ACCIDENT

Location: Sharm El Sheikh Airport, South Sinai
Date: January 3, 2004
Time: 0246 UTC, 0446 Local Time
Aircraft: Flash Airlines, Flight FSH 604,B737-3Q8, SU-ZCF.

## B. AIRCRAFT MAINTENANCE RECORDS GROUP

## C. SUMMARY

On January 3, 2004, about 0246 UTC, Flash Airlines flight FSH604, a B737-3Q8, SU-ZCF plunged into the Red Sea shortly after takeoff from Sharm El Sheikh International Airport (SSH) in South Sinai, Egypt. The flight was a passenger charter flight to Charles de Gaulle Airport (CDG), France with a stopover in Cairo international Airport (CAI) for refueling. Two cockpit crewmembers (Pilot and Co-pilot), three cabin attendants and 143 passengers ( 135 French and 8 Egyptian) onboard were killed. The airplane was destroyed due to impact forces with the red sea.

On January 11, 2004, the Aircraft Maintenance and Records Group convened at Flash Airlines Headquarter in 166b El Hegaz St, Heliopolis, Cairo Egypt in order to meet and interview Flash Airlines Technical Director and his staff. They collected all documents and records available for the subject aircraft. The rest of the aircraft records were delivered to the Accident Investigation Team on January 14, 2004. The Aircraft Maintenance and Records Group examined Flash Airlines maintenance program and the airplane records of SU-ZCF. The Aircraft Maintenance and Records Group completed the field review and examination on January 26, 2004.

The Aircraft Maintenance and Records Group performed a review of airworthiness directives, maintenance program , weight and balance report, supplemental type certificates, maintenance discrepancies, and contracts. Results of these reviews are summarized in this report.

All Interviews are attached to Appendix A of this report.

## D. DETAILS OF THE INVESTIGATION

### 1.0 Flash Airlines Air Operator Certificate (AOC)

Flash Airlines is approved as air operator (charter air carrier) under ECAR 121 by the ECAA, and operating under approval no 018.

Flash Airlines has its main office in Cairo, Egypt at 166b El Hegaz St. Heliopolis . Beginning in 2000, Flash Airlines leased the first B737-300 from the International Lease Financial Cooperation ILFC. In June 2001 another B737-300 from ILFC was added to Flash Airlines fleet which made the company fleet two aircraft the same type. The Operations Specifications was issued to the company in Feb 2000 and last revision was on October $29^{\text {th }} 2003$.

### 2.0 Aircraft History

Per Egyptian Civil Aviation Safety and Security Authority (ECASSA), civil aviation aircraft registration records , the International Lease Financial Cooperation (ILFC) leased the accident aircraft, serial number 26283, to Flash Airlines on May 14, 2001. It was registered in Egypt on June 17, 2001 under tail number SU-ZCF to be operated by Flash Airlines. The subject aircraft basic information as following:

| Aircraft Type | $:$ B737-3Q8 |
| :--- | :--- |
| Minimum Crew | $: 2$ (Pilot and Copilot) |
| Registration Mark | $:$ SU-ZCF |
| Serial Number | $: 26283$ |
| Manufacture Date | $:$ October 1992 |
| Line Number | $: 2383$ |
| Variable No | $:$ PQ294 |

Interior Configuration
ECAA Minimum Number of Flight Attendant
: Total 148 Economy Class
: 3

### 3.0 Aircraft Maintenance

### 3.1 Maintenance Program Summary- Flash Airlines B737-300

Flash Airlines has developed their customized Maintenance Program . The Maintenance Program last revision was issued on January 20, 2003 and approved by the Egyptian Civil Aviation Safety and Security Authority (ECASSA), Airworthiness Central Administration under approval No MOCA/FLASH/737-300/MP/R2/03. This Maintenance Program was incorporated guidance from Boeing Maintenance Planning Document (MPD) Revision July 2002.

The Periodic Service Check is accomplished on layover. The check is performed as a walk-around, visual inspection and servicing when necessary.

The Routine Inspection is performed every 250 flight-hours (A Checks). A Routine Inspection Procedures Index is used to assure the check is completed. The Inspection consists of a visual inspection of the aircraft's major components, servicing, operational and functional checks.

The Maintenance Program contains subparts related to:
1- Line Maintenance Checks: Transient, Daily and Weekly Checks.
2- "A" Checks which should be carried out at 250 Flight Hours Interval and its multiples. The following chart will show how are the "A" checks cycled:

| "A" Check Cycle <br> (250 Flight Hours Intervals per Cycle - 16 "C" Check) |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Check | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 |
| A | X | X | X | X | X | X | X | X | X | X | X | X | X | X | X | X |
| 2A |  | X |  | X |  | X |  | X |  | X |  | X |  | X |  | X |
| 4A |  |  |  | X |  |  |  | X |  |  |  | X |  |  |  | X |
| 8A |  |  |  |  |  |  |  | X |  |  |  |  |  |  |  | x |

3- "C" Check which should be carried out every 4000 flight hours and its multiples. The following chart will show how are the " C " checks cycled.

| "C" Check Cycle |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| (4000 Flight Hours Intervals per Cycle ) |  |  |  |  |  |  |  |  |
| Checks | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| 1C | x | x | x | x | x | x | x | x |
| 2C |  | x |  | x |  | x |  | x |
| 4C |  |  |  | x |  |  |  | x |
| 6C |  |  |  |  |  | x |  |  |
| 8C |  |  |  |  |  |  |  | x |

4- Components: This section contains general information on selected airframe and engine components. They are Condition Monitoring, On Condition or Hard Time.
5- Structure Inspection which should be carried out every 24000 Flight Hours. Structural inspections are performed in accordance with guidelines set down by the manufacturer Boeing MPD.
6- Corrosion Prevention Control Program (CPCP)
7- Pylon Inspections (ATA 54) the 15 Months and 45 Months Checks

The checks and inspection times can not be exceeded except by using the short term escalation as authorized per the Operations Specifications D95 issued by ECASSA to Flash Airlines and considered as a part of the air operator certificate AOC No 18.

The last "A" check accomplished by Flash Airlines and the last "C" check and Structural inspection carried by Braathens Engineering and Maintenance for the SU-ZCF were as follows:
"8A" Check : December 12, 2003 at 25423:50 Flight Hours
"7C" Check : From Nov 3 - Dec 21, 2002 at 23531 Flight Hours

Last SI Check : From Nov 3 - Dec 21, 2002 at 23531 Flight Hours

Last 15 M Chk : From Nov 3 - Dec 21, 2002

Last 45 M Chk: From Nov 3 - Dec 21, 2002

Copy of the checks done on the aircraft is attached (attachment 01)

### 3.2 Maintenance Time Limitations

Scheduled maintenance checks are approved by ECASSA (Flash Airlines Operations Specifications D88), and are in accordance with the Boeing 737-300 Maintenance Planning Documents MPD ${ }^{1}$.

[^16]Transient Check:
Daily Check:
7 days check:
Check "A" Systems and multiples: Every 250 Flying hours and multiples.
Check "C" Systems and multiples: Every 4000 Flying hours.
Structural Inspections: Every 24000 Flying hours

### 3.3 Aircraft Summary

Total Hours at Time of Accident: 25603 Flight Hours
Total Cycles at Time of Accident: 17976 Flight Cycles

### 3.4 Weights and Balance Summary

According to the Egyptian Civil Aviation Regulations, ECAR 91 Appendix H attachment 1 the aircraft has to be reweighed every three years. Furthermore, aircraft must be reweighed if the effect of modifications on the mass and balance is not accuratly known. Flash Airlines aircraft was weighed last time on December 19, 2002 in Braathens SAFE, Stavangar, Norway. and recalculated by Flash Airlines after the reenforced cockpit door modification installation on November $1^{\text {st }}, 2003$, and the results were as follows.

| Empty Weight | $:$ | 70794 lbs |
| :--- | :--- | :--- |
| Moment | $:$ | 45921358.6 lb. in |
| \% AMC | $:$ | $17.42 \%$ |

### 3.5 Engines: CFM56-3C-1

Engines are maintained in accordance with Flash Airlines Maintenance program and are based on the life cycle limits of the rotating components. CFMI Engine maintenance manual together with the applicable Service Bulletins and engine teardown data determine these limits. Overhauls are performed at the SNECMA MOROCCO Workshop or other authorized Certified Repair Station.

|  | $\frac{\text { Engine Position 1 }}{\text { (Left Side) }}$ |  | $\frac{\text { Engine Position 2 }}{\text { (Right Side) }}$ |
| :--- | :--- | :--- | :--- |
|  |  |  |  |
| Serial Number (ESN) | 857352 | 856481 |  |
| Time Since New (TSN) | 25314 hours | 26045 hours |  |

| Cycles Since New (CSN) | 17815 Cycles | 17523 Cycles |
| :--- | :--- | :--- |
| Date of Installation on SU-ZCF | August 1998 | Jan 3, 2003 |
| Time Since Last O/H | 8741 Hours | 1828 Hours |
| Cycles Since Last O/H | 6188 Cycles | 909 Cycles |

Engine Disks and First Limiters Status as per attached (attachment 02)

### 3.6 Engine Monitoring System

Flash Airlines engines are monitored as per the manufacturer (CFMI) engine condition monitoring program (Sage Trend Analysis program). Sage is a set of programs which collectively provide the functionality to perform standard condition monitoring of CFMI engines. Sage is designed to work in an interactive environment with the major analytical calculations performed at scheduled times throughout the day.
By reviewing the engine condition monitoring trend reports for both engines, they showed no deviation or important shift, the EGT margin is considerable ok. Engine Condition Monitoring cruise trend sheet is attached (attachment 14)

### 3.7 Flight Data Recorder/ Cockpit Voice Recorder.

| Description | P/N | S/N | Test Date Workshop |  |
| :--- | :--- | :--- | :--- | :--- |

### 3.8 Aircraft Status

### 3.8.1 Minimum Equipment List (MEL)

Flash Airlines Customized Minimum Equipment List CMEL was approved by the ECASSA on Feb 23 ${ }^{\text {rd }}$, 2002 under approval number ECASSA/FLASH/MEL/737300/02/02 according to MMEL ${ }^{2}$ R40, meanwhile another revision according to the last Master Minimum Equipment List (MMEL) revision 45 is currently under approval by the ECAA.

[^17]
### 3.8.2 Aircraft Condition Report (A/C deferred defects)

No deferred items were recorded in the aircraft deferred snags log Book

### 3.8.3 Type Certificate Data Sheet

FAA "Type Certificate Data Sheet" number A16WE (revision 28, dated October 29, 1999) for B737-300 series airplanes was reviewed for compliance conditions and limitations. No discrepancies were noted. Type certificate Data Sheet attached (attachment 15)

### 3.8.4 Supplemental Type Certificates

Supplemental Type Certificates supplied by Flash Airlines were reviewed. One Supplemental Type Certificate was issued to install a Matsushita Audio Entertainment System in accordance with General Aerospace Engineering Order No GA-23-1042. STC attached (attachment 16)

### 3.8.5 Airworthiness Directives (AD) Summary and Service Bulletins (SB) Summary

The Airworthiness Directives compliance status list dated January $12^{\text {th }}, 2004$ (attachment 03) submitted by Flash Airlines was reviewed with special concentration on AD's carried out after the aircraft was leased by Flash Airlines.
The previous AD's Status which was forward to Flash Airlines during the aircraft delivery was reviewed with special attention to those AD's which had an open or repetitive status.
All listed Airworthiness Directives and Service Bulletins have been complied with no discrepancies noted.
Service Bulletins compliance status attached (attachment 17).

### 3.8.6 Time Controlled Components

Time Controlled items listed on the Boeing 737-300 Maintenance Program, including task card number, part/serial numbers, and the time interval, were reviewed. The listing by task card noted categories (inspections, functional check, restoration, or scrap). Flash Airlines has no exceedance for the MPD recommendations. No discrepancies were noted. Components list replaced by Flash Airlines attached (attachment 04)

### 3.8.7 Prior Discrepancies/Accidents Involving SU-ZCF

Per Flash Airlines records, no previous accidents were reported for the accident aircraft.

### 3.8.8 Logbook Forms

The original aircraft Technical Log Book sheets were reviewed for the last three months from September 27, 2003 through December 2003 for discrepancies, no trends or discrepancies noted. The list of the reviewed Technical Log Book sheets is attached:

Few number of pilot reports are recorded. Some corrective actions recorded by the maintenance staff without pilot reports. Copy of the Tech Log Book entry listing is attached (attachment 05)

Copies of the Technical Log Book sheets following the original copies (from Dec 27, to Dec 31, 2003) were reviewed also. The following are the review results:

- The Line Maintenance checks (transient, PDC and Daily) are properly carried out and recorded by the certified staff.
- All Pilots acceptance are recorded.
- Pilots reports are very limited, however many corrective actions are recorded by the maintenance staff.
- Some Technical Log Book sheets are missed From serial no 1998 up to the accident flight. (Shown as per attached schedule)

### 4.0 Maintenance Participants

Prior to the accident, the most recent scheduled maintenance performed on the accident aircraft was (8A check) done by Flash Airlines, Cairo base on December 11, 2003. Also, the PDC check was carried out by Flash Airlines Engineer at SSH station just before the accident. Due to the unavailability of the missed technical log book sheets, an interview, and document review were conducted to obtain information about the maintenance performed at this station before the accident flight.
The on board ground engineer said that there weren't any abnormal problem with the aircraft during the flight to SSH from VCE. And nothing was reported from the pilot. Interview attached (attachment 06)

### 4.1 Flash Airlines Approved Maintenance Organization (AMO)

Flash Airlines is also approved under ECAR 145 as a repair station . The approval number is CAI/FLASH?AS/1/2001. The certificate is valid until July $30^{\text {th }}, 2004$ and was issued on July 31, 2001. The certificate is limited to line maintenance up to the 8A check for the B737-300. Flash Airlines maintenance base is Cairo international Airport.

Flash Airlines coordinates the maintenance program through its ECAR Part 145 certificate. The Company General Maintenance Manual (GMM) provide guidance related to the Aircraft Maintenance program as the Maintenance Procedures, Maintenance staff Training... etc.

Personnel working on Flash Airlines Fleet at the various maintenance facilities must be familiar with the policies and procedures spelled out in the company GMM. The Quality Control Manager puts the newly hired employees through a twelve-hour Indoctrination Course. The Indoctrination course Flash Airlines policy and procedures, and training practices. It is accomplished before maintenance engineer begins to work at the Flash Airlines facility. The training is documented on a maintenance training attendance record, recorded on the employee's training file.

### 4.2 Contracted Repair Station Listing

- EgyptAir Maintenance and Engineering
- Braathens Maintenance and Engineering
- Snecma Morroco Engine Services.

### 5.0 Personnel Training and Authorization

According to ECAR 65 the requirements for granting authorization for ground engineer are as follow:

1- Graduation from Faculty of Engineering or an approved training institute.
2- Passing the approved Basic training Course at approved Training Center or institute.
3- On Job Training for 18 months.
4- Passing written, practical and oral exams by the authority for License without Type Rating (LWTR).
5- Passing an approved training course for a specific type airframe and engine.
6- On Job Training (OJT) on the type airframe and engine for 9 months.
7- Attendance of training course for the company exposition procedure manual.
8- Passing oral and practical examination in front of the Company Examination Board (approved by the authority)
9- Getting the company approval.
Flash Airlines maintains its training program in compliance with Egyptian Civil Aviation Regulation requirements. The Maintenance Director and the Quality Control Manager have joint responsibility for assuring all required training is performed and recorded. Indoctrination training proceeds an employee's start date. The employee is given a 4-hour introduction course that trains one on Flash Airlines maintenance policies and procedures. The training will be documented on a maintenance training attendance record and maintained in the employee's training file.

The aircraft systems training for the A \& C Engineers is accomplished through formal systems training and On-the-Job Training (OJT) Worksheets.

Engineer Mostafa Erfan Askr does the last flight release.

Engineer Mostafa was graduated from the National Civil Aviation Training Organization on September a6th 1972. He worked as a mechanic for the Kuwait Airways for twenty years during which he received the following training courses:

1- B 747-269B Mechanics Familiarization during the period between Feb $17^{\text {th }} 1979$ to March $3^{\text {rd }}$ 1979. (Kuwait Airways).
2- Airbus Mechanics Familiarization Course during the period between October $6^{\text {th }}$ to October $18^{\text {th }} 1984$ (Kuwait Airways).
3- B767 Mechanics Familiarization A\&C Course during the period between February $7^{\text {th }}$ to February $19^{\text {th }}, 1987$ (Kuwait Airways).

In 1991 he took the Cessna 188 course at DEVCO training center, then he got his Egyptian license without type rating (LWTR) No 1525 on August $1^{\text {st }} 1992$ which is valid until July $27^{\text {th }}, 2004$.

He joined Flash Airlines two years ago, during this two years he had the following training and exams:

1- B737-300 type course at EgyptAir approved training center during the period between December $22^{\text {nd }}$, 2002 to February $27^{\text {th }}, 2003$.
2- Basic Indoctrination Course during the period between 13-14 June 2003.
3- An on Job Training for 9 months on Flash Airlines B737-300 fleet.
4 - An approval authorization exam for the engine on November $2^{\text {nd }}, 2003$ and for the airframe November $3^{\text {rd }}, 2003$.

His approval No: 014 Valid until: July 26 ${ }^{\text {th }}, 2004$ Issued on: Nov $28^{\text {th }}, 2003$
LWTR No: $1525 \quad$ Valid until: July $27^{\text {th }}, 2004$ issued on: August $1^{\text {st }}, 1992$

### 6.0 Contracts

### 6.1 Flash Airlines and EgyptAir Approved Maintenance Organization Contract

The contract between Flash Airlines and EgyptAir Maintenance and Engineering Approved Maintenance Organization (attachment 07) was signed January , 2000. There are 15 agreement statements throughout the contract identifying conditions in which the two companies will work together.
Per the contract, EgyptAir will perform maintenance routine checks (A check and its multiples and C Checks and its multiples) and any requested AD's accomplishment on the B7373-300 operated by Flash Airlines.
Flash Airlines provides the work package for the required routine check including the routine task cards, engineering orders weather for Airworthiness Directives, Service Bulletins, or modifications as well as other non-routine task cards that may be required to be accomplished concurrently with the routine check, in addition to any rectified defects by EgyptAir during the check.

EgyptAir is an approved maintenance organization as per ECAR 145 under approval No CAI/EGYPTAIR/AS/01/98 issued by ECASSA

### 6.2 Flash Airlines and Braathens Maintenance and Engineering Contract.

The contract between Flash airlines and Braathens Maintenance and Engineering in Stavangar, Norway (attachment 08). It became effective on November 3rd, 2002. There are thirty statements of understanding and two Appendices that explain the conditions of the Agreement.

Flash Airlines provides the required work scope as per their approved maintenance program. Braathens Maintenance and Engineering supplies the necessary consumables, routable parts, and equipment.

Braathens Maintenance and Engineering is approved as Per ECAR 145 approved maintenance organization under approval CAI/BRAATHENS/AS/1/2002.

### 6.3 Flash Airlines and SNECMA MOROCCO ENGINE SERVICES.

The contract between Flash Airlines and SNECMA MORROCO ENGINE SERVICES (attachment 09) was signed on November $7^{\text {th }}$, 2002. There are 22 agreement statements throughout the contract identifying conditions in which the two companies will work together.

Per the contract, Flash Airlines and Snecma MORROCO ENGINE SERVICES have entered into this agreement to stipulate and regulate terms and conditions for repair/overhaul of Flash Airlines CFM56-3C-1 Engines rated 22 klbs.
According to the agreed workscope, it includes repair, engine performance restoration, and application of any applicable AD's.

SNECMA MOROCCO ENGINE SERVICES is approved as Per ECAR 145 approved maintenance organization under approval CAI/SNECMA MOROCCO/AS/1/2002

### 7.0 Maintenance Performed on the A/C before the accident flight.

### 7.1 Maintenance done by Flash Airlines Tech Staff at Cairo Base

The Last Check carried out on the accident aircraft was an 8A check. The check was performed by Flash Airlines Technical staff at Cairo base station. The check workpackage included visual inspection, servicing, and operational checks. A routine borescope inspection for the HPT nozzles guide vanes and the combustion chamber was performed on both engines by EgyptAir with no findings. The workpackage was reviewed with no discrepancies.

### 7.2 Transient Check carried out for the Flight VCE/SSH

A transient check was carried out in VCE by engineer Motaz Awad on January 2 ${ }^{\text {nd }}, 2004$ a copy of the interview with him is attached (attachment 06)

### 7.3 Last PDC Carried out for the Accident Flight

On January $3^{\text {rd }}, 2003$, aircraft SU-ZCF, a daily check was performed in accordance with the approved checklist as per the company maintenance schedule at SSH station just before the flight. The check was carried out by the accident flight, on board engineer (Eng Mostafa Askar).

### 7.4 Aircraft Refueling before the Accident Flight and investigations done after the accident.

The Refueling was done for the accident aircraft on January $3^{\text {rd }}, 2004$ between 03:50 and 04:00 local time (UTC +2) for the quantity of 3500Liters by truck no 4432 belonging to Misr Petroleum Company (service invoice is attached) attachment 10.

The same truck had refueled the following airplanes on the same date:

- EgyptAir aircraft A320 SU-GBF at 02:05 LT before the accident aircraft.
- Taroum aircraft YR-GGX at 04:20 LT after the accident aircraft.
- EgyptAir aircraft SU-GCD at 05:10 LT after the accident aircraft.

After the aircraft accident, Three fuel samples had been drawn from the Misr Petroleum fuel truck on January $3^{\text {rd }}, 2004$ at 12:45 local time. One of them was used for a dehydrated Copper Sulfate capsule field inspection for fuel water content, which was satisfactory (attachment 11). The two others samples were sent to the following laboratories for analysis:

- The Egyptian Petroleum Research Institute Nasr City, Cairo (attachment 12).
- Misr Petroleum Company, Ghamra Research Center Laboratory (attachment 13).

The Egyptian Petroleum Research Institute (EPRI) performed the Jet (A-1) fuel analysis, ASTM distillation and ASTM D-86. The results of these analyses show that all the values are within limits except for the water content, ppm, which is 48 , and the max is 30 .

The Misr Petroleum Co, Ghamra Research Center Laboratory performed the same analyses done by (EPRI), all the results comply with the requirements of DES-STAN 9191 issue 4 (DERD 2494) and the joint fueling systems "Checklist" specifications for JET A-1 issue 19 Sept, 2002.

## Appendix A

## Attachment Listing

Attachment 01: List of Checks done on the accident aircraft.

Attachment 02: Engine Disks and first limiters status
Attachment 03: Airworthiness compliance status.
Attachment 04: Components list replaced by Flash Airlines.

Attachment 05: Copy of the Tech Log Book Entry Listing.
Attachment 06: Eng $\square$ Interview.

Attachment 07: EgyptAir Contract

Attachment 08: Braathens Engineering and Maintenance Contract.

Attachment 09: Snecma Morocco Contract

Attachment 10: Fuel Service Invoice.

Attachment 11: On spot fuel field inspection.
Attachment 12: Egyptian Petroleum Research Institute Analyses Report.
Attachment 13: Misr Petroleum Co, Ghamra Laboratory analyses report.
Attachment 14: Engine Condition Monitoring Cruise Trend Sheets.
Attachment 15: Type Certificate Data Sheet.

Attachment 16: Supplemental Type Certificate, STC.

Attachment 17: Service Bulletins compliance list

Service Bulletins compliance list
S Dates

## Exhibit B

## Flight Data Recorder (FDR) <br> Group Factual Report

# Ministry of civil aviation 

Accidents Department
Egypt, Cairo
October14, 2004

# Group Chairman's Factual Report - Flight Data Recorder 

## ACCIDENT

Location:<br>Date:<br>Time:<br>Operator:

Red Sea off Sharm el-Sheikh
January3, 2004
2:45:06 GMT
Flash Airlines - Flight 604

The group convened at MCA headquarters in Cairo from January16, 2004 for readout of the FDR. The readout included transcription of the accident flight data. In addition, a transcription of the entire 25-hour contents of the FDR was accomplished.

## SUMMARY

On January 3, 2004, about 02:45:06 UTC, 04:45:06 Local time, Flash Airlines flight FSH604, a Boeing 737-300, Egyptian registration SU-ZCF, operated by Flash Airlines, crashed into the Red Sea shortly after takeoff from Sharm el-Sheikh International Airport (SSH) in South Sinai, Egypt. The flight was a passenger charter flight to Charles de Gaulle Airport (CDG), France with a stopover in Cairo international Airport (CAI) for refueling. Flight 604 departed from Sharm el-Sheikh airport with 2 pilots (Captain and First Officer), 1 observer, 4 cabin crew, 6 off-duty crew members and 135 passengers on board. The airplane was destroyed due to impact forces with the red sea with no survivals.

## Details of Investigation

- The accident airplane's flight data recorder (SSFDR), part number 980-4120-DXUN S/N 10069, was retrieved from the Red Sea on January16, 2004 by the French Navy. The FDR was immersed in water and sealed in an ice chest and transported to MOCA, accident investigation laboratory at Cairo.
- Readout of the FDR was accomplished using the laboratory's playback hardware, Hand held Down Load unit manufactured by ALLIED SIGNAL Part No. 964-0446-001 and recovery/ analysis/ presentation system (RAPS) software.
- Inspite of the damage that had occurred to the external case of SSFDR, the internal solid state memory was in good condition and all the available data was retrieved. RAPS considered the recorded signal and data quality to be very good.
- Data plots and tabular listings of each data parameter for the entire accident flight are included in this report. The entire 25-hour contents of the FDR were also transcribed, and the data provided to the parties to the investigation.

After the cockpit voice recorder (CVR) timing had been compared to the SSFDR vhf microphone keying and Autopilot disengages warning, a time correlation was developed.

## Unreliable parameters

- Control Wheel Position

The position of the control wheel is sensed by a position transmitter mounted under the flight deck floor. The transmitter measures the rotation of a shaft that is connected to the lateral control system with a cable and pulley arrangement. The body of the transmitter is cylindrical and is held in place by a clamp. The output may be adjusted by rotating the body of transmitter within clamp which is then tightened. The recorded position of the control wheel tended to follow the recorded position of the ailerons, and therefore appears to have the correct profile. However there was an offset or bias between the recorded position and the expected position. The value of the bias changed at irregular intervals, often when large control wheel inputs were made, and also every time that a control wheel freedom-of-motion check was conducted prior to takeoff. The shifting bias was evident in all 25 hours of FDR data.

## - Left Engine N1

The fan speed of the left engine appears to behave normally during the first 17 hours of recorded data. During the last 8 hours (including the accident flight), the parameter recording fan speed alternates between two fixed values. All other engine parameters
for both the left and right engine are operating normally. The aerodynamic performance and simulation match discussed in section 1.16 indicates that the left engine was operating normally.

## - Slat \#1 Mid Extend Discrete

Slats position is recorded by three discrete parameters as follows:
o "Slats full extended"
o "Slats in transit"
o "Slats mid extended"
. Normally, during cruise, the slats are up, during takeoff, the slats are in the midextend position to provide increased low-speed lift capability. During landing, the slats are normally in the fully extended position to further increase low-speed lift capability. The position of each slat is indicated by discrete parameters on the FDR. With the exception of the "LE Slat 1 Mid Extend" parameter, all of the slat indications recorded on the FDR change in a consistent manner

## Comments

1) The transition of the Air/Ground discrete parameter from "Ground" to "Air" had occurred at 2:42:33 GMT, the last recovered data was recorded at 2:45:5 GMT.
2) TOGA mode had been engaged at 2:42:02 GMT for two seconds, and then disengaged. While checking the TOGA mode operation all over the FDR 25 Hr. Data, We notice that every time the mode engaged, one second or two seconds later disengage.
3) During takeoff with the aircraft magnetic heading constant, the right aileron indication was up and the left aileron indication was down.
4) Heading Select and Level Change modes had been selected as Flight director modes.
5) The FDR data indicates that the airplane was turning to the left after takeoff, and rolling back towards wings level before the autopilot engagement.
6) The autopilot had been engaged at 2:43:59 GMT and disengaged at 2:44:02GMT. At 2:44:03 GMT, the autopilot disengage warning was recorded.
7) At autopilot engagement, the Heading Select Mode was disengaged and reverted to CWS R Mode.
8) Between the time of the autopilot engagement and disengagement, the FDR records momentary aileron surfaces movements. The right aileron deflected to 7.2 degree TEU for one second.
9) After autopilot disengagement, the aircraft had turned to the right and on the other hand the ailerons repetitively moved between the neutral and the roll right direction.
10) At $2: 44: 58 \mathrm{GMT}$, the aircraft roll angel reached $111.094^{\circ}$ to the right, next second both ailerons reversed their directions and initiated aircraft recovery.
11) Hydraulic pressure, Engine Oil Quantity, Speed Brake Handle Position, Selected Heading and Selected Course no. 1 Parameters were retrieved according to Boeing Document "Enclosure B-H200-17884-ASI"

## Attachments:

A- Attachment 1, Tabular data of the accident flight.
B- Attachment 2, FDR Plots
C- Attachment 3, Five plots represent FDR and CVR correlation.

Note: Soft Copy for all 25 hours FDR data is available at MCA upon request

Attachment 1, Tabular data of the accident flight.

## Group Chairman's Factual Report - Cockpit Voice Recorder

## ACCIDENT

| Location: | Red Sea off Sharm el-Sheikh |
| :--- | :--- |
| Date: | January3, 2004 |
| Time: | 2:45:06 GMT |
| Operator: | Flash Airlines - Flight 604 |

The group convened at CVR/FDR laboratory at MCA headquarters -
Cairo for retrieval of CVR conversation and aural sounds.

## SUMMARY

On January 3, 2004, about 02:45:06 UTC, 04:45:06 Local time, Flash Airlines flight FSH604, a Boeing 737-300, Egyptian registration SU-ZCF, operated by Flash Airlines, crashed into the Red Sea shortly after takeoff from Sharm el-Sheikh International Airport (SSH) in South Sinai, Egypt. The flight was a passenger charter flight to Charles de Gaulle Airport (CDG), France with a stopover in Cairo international Airport (CAI) for refueling. Flight 604 departed from Sharm el-Sheikh airport with 2 pilots (Captain and First Officer), 1 observer, 4 cabin crew, 6 off-duty crew members and 135 passengers on board. The airplane was destroyed due to impact forces with the red sea with no survivals.

## Details of Investigation

- The accident airplane’s Cockpit Voice data recorder (CVR), Fairchild, Part no. 93A100 - 80, serial no. 57994 was retrieved from the Red Sea on January17, 2004 by the French Navy. The CVR was immersed in water and sealed in an ice chest and transported to MCA, accident investigation laboratory at Cairo.
- Readout of the CVR was accomplished using the laboratory's playback hardware and software as follow:

## Download Unit:

A100 CVR play back Deck - Store 4DS
Audio Analysis System:
MPL 1024, 12 Channel Microphone Mixer - Samson
Filter : PCAP II (Samson)
Amplifier: Samson - Servo-550 Studio Amplifier
Software:
Vegas 4 - Sound Forge 6 -PCAP II

- The recorder consisted of four channels of audio information.

Channel One:
Channel Two:
Channel Three:
Channel Four:

First officir hot mic.
Area Mic.
Observer hot Mic.
Captain hot Mic.

- After the initial retrieved sound task was completed another effort was undertaken with the assistance of BEA expert as follows:
o The output signal from the tape deck playback machine was too low compared to the recording on the same conditions in BEA. This problem was solved by increasing the output level when the screw of the adjustable gain control was turned clockwise.
o The sensitivity of the acquisition audio card of the PC was not good enough to capture correctly the audio signal coming from the tape deck player. This problem was solved by changing the value of the "Variable Signal Levels" on the hardware setting of the audio card, from the manufacture value +4 to -10 . The gain was increased and the input signal amplified.
o The speed of the tape was not correct with an interference of the power ( $115 \mathrm{~V}, 400 \mathrm{~Hz}$ ) measured at 375 Hz . It was not possible to adjust properly the speed of the tape with the device installed. This problem is solved by resembling the wave file with a correct ratio $(400 / 375=1.0665)$.
o Some high frequencies were missing when doing the spectrum analysis. This problem was solved by using a sampling rate of 32000 kHz instead of 22000 kHz .
o The alignment of the head installed on tape deck player was checked, adjusted and was found satisfactory prior to playback the tape.

A new copy of the CVR was performed. This recorded copy is satisfactory.

- Due to the effect of aircraft power $(115 \mathrm{~V}, 400 \mathrm{~Hz})$ on the tape speed, the data had been retrieved at a sample rate 34128 HZ. Recording time of the Subject CVR measured found 31 min . and 13.7 sec . and the frequency was 402 HZ

## Comments

- Before start check list, below the line, Engine start, after start check list, and before Takeoff check list down to strobe lights are carried out.
- During flight control check at 02:37:40, two consecutive sounds had occurred, following at 02:37:41 the Captain had announced "turning to the right".
- Before the engine started, sound similar to Cockpit door operation was heard and no body other than the Captain, the First officer and the Extra crew1 was in the cockpit till the end of the CVR tape.
- At 02:42:43, the Captain requested for "Four Hundred Heading Select". One second later the First Officer acknowledged "Four Hundred Heading Select"
- At 02:42:484, the Captain had asked for "Level Change". One second later the First Officer repeated "Level Change".
- At 02:43:04 and at 02:43:11, the captain had announced "Left Turn". One second later the First Officer repeated " Left turn to establish Three Zero Six Sharm VOR"
- At 02:43:55, the Captain had asked for "Autopilot". At 02:44:00, The First officer announced "Autopilot in command" and at 02:44:02, the sound of autopilot disengages warning was heard.
- At 02:44:05, the Captain had asked for "Heading Select". At 02:44:07, the First Officer repeated "Heading Select"
- AT 02:44:27, the First Officer had announced "Turning right Sir" and again at 02:44:31, he confirmed "Aircraft is turning right".
- At time 2:44:35 Captain said "turning Right?"
- At time 2:44:37 Captain said "how turning right"
- At 02:44:41.7 and at 02:44:43.4, the Captain had asked for "Autopilot", and at 02:44:44 the First Officer replied "Autopilot in command"
- At 02:44:46, the Captain had asked for "Autopilot", and at 02:44:56, the First officer replied "No autopilot Commander" but again the Captain in command asked for "Autopilot".
- The phrase "Come out" was repeated three times by the captain at 02:44:41, 02:44:53.4 and 02: 45:04.3
- Extra crew 1 did not interfere during flight progress except at 02:44:58.8 when he had been announced "Retard Power, Retard Power, Retard Power"

Transcript of a Fairchild A-100 cockpit voice recorder (CVR), serial no. 57994 installed on a B-737-500, SU-GZF, which was involved in a descent and collision into the Read Sea near Sharm on Jan, 2004

Accident flight plan (copy of the flight plan referred to by ATC at 02:38:05 in the CVR transcript)

## Exhibit C CVR Group Factual Report

## Spelling corrections

Two spelling corrections should be made:

- The phrase "02:34:25 Attendant: "on behalf of Captain Kheder" (in page 269)
- should read "02:34:25 Attendant: "on behalf of Captain Khedr"
- The phrase "advice ready for departure" (in page 273)should read " advise ready for departure "

## Exhibit D

## Airplane Performance Group <br> Factual Report

# Ministry of civil aviation <br> Accidents Department <br> Egypt, Cairo 

October14, 2004

## Group Chairman's Factual Report - Performance

## A. ACCIDENT

Location: $\quad$ Red Sea off Sharm el-Sheikh
Date: January3, 2004
Time: 2:45:06 GMT
Operator: $\quad$ Flash Airlines - Flight 604

The group convened at MCA headquarters in Cairo from January15, 2004 for performance Factual Data collection

## B. SUMMARY

On January 3, 2004, about 02:45:06 UTC, 04:45:06 Local time, Flash Airlines flight FSH604, a Boeing 737-300, Egyptian registration SU-ZCF, crashed into the Red Sea shortly after takeoff from Sharm el-Sheikh International Airport (SSH) in South Sinai, Egypt. The flight was a passenger charter flight to Charles de Gaulle Airport (CDG), France with a stopover in Cairo international Airport (CAI) for refueling. Flight 604 departed from Sharm el-Sheikh airport with 2 pilots (Captain and First Officer), 1 observer, 4 cabin crew, 6 off-duty crew members and 135 passengers on board. The airplane was destroyed due to impact forces with the Red Sea with no survivals.
The airplane had departed from Sharm el-Sheikh runway 22R and was air born at 02:42:33 UTC, approximately $2 \frac{1}{2}$ minutes prior to the crash, and had been cleared for a climbing left turn intercept the 306 radial from the Sharm el-Sheikh VOR station located just north of runway 22R. This climbing turn allows departing flights to gain sufficient altitude before proceeding over higher terrain located along the flight path to Cairo. Flight 604 was operating in Egyptian airspace as a charter flight operating under the provisions of Egyptian Civil Aviation Regulations Part 121

## C. DETAILS OF THE INVESTIGATION

The purpose of the Aircraft Performance Group (ACPG) is to collect the factual information to determine and analyze the motion of the aircraft and the physical forces that produce that motion. In particular, the Group attempts to define the aircraft position and orientation throughout the flight, and determine its response to control inputs, system failures, external disturbances, or other factors that could affect its trajectory. The data the ACPG uses to obtain this information includes but is not limited to the following:

- Wreckage location and condition.
- Aircraft Surveillance Radar (ASR 12) Radar Data.
- Digital Flight Data Recorder (DFDR) data.
- Cockpit Voice Recorder (CVR) information.
- Weather information.
- Weight and Balance Data.
- Tests and Researches

## C. 1 Wreckage Location and Condition:

Refer to the Wreckage and Impact Factual Information

## C. 2 Radar Data

Sharm el-Sheikh Radar

- General Specifications:

ASR 12 Radar (Aircraft Surveillance Radar)
Secondary 250 nm
Primary 60 nm
15 Revolution Per minutes approximately (Scan time $=4.13 \mathrm{sec}$ )
Radar site location: 2758.057n/ 03421.985e (Lat. 27.96762 Degree north, Long. 34.36642 Degree east)

Radar Elevation: 299.3 ft

## C3. Digital Flight Data Recorder (DFDR) data.

Refer to FDR Factual Report

## C4. Cockpit Voice Recorder (CVR) information.

Refer to FDR Factual Report

## C5. Weather Information

Sharm El Sheikh does not provide Automatic Terminal Information Service (ATIS).
The SSH weather at 0200Z was reported as:
270 degrees at 06 knots, ceiling and visibility OK (CAVOK), temperature 17 degrees Celsius, dew point minus 6 degree Celsius, altimeter 1011 HectoPascals (hPa), No significant change (NOSIG).

The SSH weather at 0300 Z was reported as:
280 degrees at 08 knots, ceiling and visibility OK (CAVOK), temperature 17 degrees Celsius, dew point minus 6 degree Celsius, altimeter 1011 HectoPascals (hPa), No significant change (NOSIG).

## C6. Weight and Balance Data.

According to the Egyptian Civil Aviation Regulations, ECAR 91 Appendix H attachment 1 the aircraft has to be reweighed every three years. Furthermore, aircraft must be reweighed if the effect of modifications on the mass and balance is not accurately known. Flash Airlines aircraft was weighed last time on December 19, 2002 in Braathens SAFE, Stavangar, Norway and recalculated by Flash Airlines after the reinforced cockpit door modification installation on November $1^{\text {st }}, 2003$, and the results were as follows.

| Empty Weight | $:$ | 70794 lbs |
| :--- | :--- | :--- |
| Moment | $:$ | $45921358.6 \mathrm{lb} . i n$ |
| \% AMC | $:$ | $17.42 \%$ |

The Flash Airlines weight and balance calculations provided to the flight crew contained the following information ${ }^{1}$ :

|  | Weight (kilograms) |  |
| :--- | :--- | :--- |
| Total Traffic Load | 11,4502 |  |
| Dry Operating Mass | 33,200 |  |
| Actual Zero Fuel Mass | 44,650 |  |
| Maximum Zero Fuel Mass | 47,627 |  |
| Takeoff Fuel | 7,000 |  |
| Actual Takeoff Mass | 51,650 |  |
| Maximum Takeoff Mass (Certificate Limi | 63,276 |  |
| Landing Mass | 49,650 |  |
| Maximum Landing Mass (Certificate Lim | 51,709 |  |

| Zero Fuel Mass Center of Gravity (CG) | $20.0 \%$ |  |
| :--- | :--- | :--- |
| Zero Fuel Mass CG Limits 3 | $8.0 \%$ Forward | $28.4 \% \mathrm{Aft}$ |
| Takeoff Mass CG | $18.0 \%$ |  |
| Takeoff Mass CG Limits ${ }^{3}$ | $6.7 \%$ Forward | $27.9 \%$ Aft |

[^18]Stabilizer Trim settings for takeoff were:

| Flaps 1 or 5 | $43 / 4$ Units |
| :--- | :--- |
| Flaps 15 | $33 / 4$ Units |

According to the Flash Airlines Flight Operations Manual Chapter 6, Paragraph 6.1.8.3, Passenger and Baggage Masses, the following chart was published:

|  | Male | Female |
| :---: | :---: | :---: |
| All flights except | 88 kg | 70 kg |
| Holiday | 83 kg | 69 kg |
| Children | 35 kg | 35 kg |

A review of the accident Load and Trim Sheet indicated a Passenger Mass of 9,450kg. If 350 kg is removed for 10 children ( $10 \times 35 \mathrm{~kg}$ ) the result is $9,100 \mathrm{~kg}$. Dividing the 125 adult passengers into the $9,100 \mathrm{~kg}$ would give an average value of 72.8 kg per adult passenger.

Using the table above, and assuming 50\% Male and 50\% Female adult passengers, the worst-case difference in weight calculation would be the following:

The average weight of male and female for all flights except would be $88 \mathrm{~kg}+70 \mathrm{~kg} / 2=79 \mathrm{~kg}$ per adult passenger.
$79 \mathrm{~kg} \times 125$ passengers $=9,875 \mathrm{~kg}$
The represents an increase in weight of 775 kg .
Using this value for Load and Trim calculations provided the following information:

```
Takeoff CG 18.2\%MAC
Zero Fuel Mass CG 20\% MAC
Takeoff Trim (flaps 5) \(43 / 4\) Units
```

These worst-case differences in values for passenger weight still fall within structural and calculated limitations for the airplane.

[^19]

## C7. Tests and Research

The FDR records the movements of the pilot's controls (e.g. control column, control wheel position and rudder pedals), the movement of the control surfaces (e.g. elevator, aileron and rudder) as well as motion of the airplane (e.g. pitch and roll attitude and heading angle). The performance evaluation was conducted to determine if the control surfaces were responding normally to the pilot's controls and if the airplane was responding normally to movement of the control surfaces.

In order to accomplish this work, Boeing's 737-300 aerodynamic simulation model was used to recreate the accident flight. The simulation calculates the response of the airplane to movement of the flight control surfaces - for example, it can calculate the roll rate resulting from a 10 degree deflection of the ailerons. The simulation has been verified by comparison against actual flight test data and was used for the design and certification of the 737-300 airplane. In addition, the simulation is the basis for 737-300 crew training simulators used around the world. It should be noted that the 737-300 simulation model is essentially a computer program that represents a nominal airplane with nominal engines. Small differences between the simulation and individual airplane's behavior are common and expected due to differences in control surface rigging, engine wear, and other normal tolerances.

## Performance Evaluation

FDR data are recorded at relatively low sample rates and are recorded from different sources, some of which have inherent biases. Because of these issues, a kinematic consistency (KINCON) process was used to supplement the FDR data and calculate additional parameters to be used in the performance analysis. Kinematic consistency analysis is a general practice for processing flight data (either flight test data or FDR data) to ensure consistency of position, speed, and acceleration data.

## C7.1 Baseline Simulation

A baseline simulation recreation of the accident flight was started just as the airplane turned onto the runway and the throttles were advanced, and the simulation was stopped at the end of the FDR data. Because the simulation can calculate the response of the airplane to control inputs, a set of control input time histories (column, wheel, and rudder movements) can be determined that results in the simulation following the same path as the accident airplane. It is important to note that this process does not use the control or surface position data recorded on the FDR, only the path information (e.g. accelerations, attitude and altitude).

Comparisons between the recorded FDR data and the simulation time history data are provided for longitudinal and lateral/directional data in Figures Figure C7-1 and Figure C7-2 respectively.

Figure C7-1 - FDR and Simulation Match Data - Longitudinal Axis

Figure C7-2 - FDR and Simulation Match Data - Lateral/Directional Axis

An examination of the baseline simulation revealed that the path of the accident airplane is consistent with the recorded motion of the control surfaces. Specifically, the extreme bank attitude that occurs towards the end of the flight is consistent with recorded motion of the ailerons.

The simulation also revealed that the motion of the control surfaces is consistent with the recorded motion of the control inputs, with the exception of control wheel

C7.2 Hypothetical Faults resulting in a rolling moment
Several hypothetical airplane system faults were examined to determine if any could have resulted in the right roll behavior recorded on the FDR. These faults included:

- Uncommanded deployment of the \#1 slat
- Uncommanded spoiler deflection to full travel (hardover)
- A spoiler disconnected from its actuator (spoiler float)
- Flap asymmetry
- Thrust asymmetry
- Unrecorded rudder motion

The hypothetical faults listed above are similar in that they each create a rolling moment unrelated to the position of the ailerons that will cause the airplane to bank. That is to say, if one of these faults had occurred, the path of the airplane would have differed from that predicted by the recorded position of the ailerons.

Multi-Purpose Engineering Cab Simulator
Additional tests were conducted at Boeing's multi-purpose engineering cab simulator or MCab . The M-Cab is similar to a flight crew training simulator in that it consists of a realistic flight deck mounted on a movable base. The M-Cab includes a visual system providing out-the-window views to the flight crew. Because the M-Cab is used to simulate the flight deck of many different Boeing models, actual flight instruments are not used. Instead, a large LCD display is programmed to simulate the flight instrument displays. Examples of the MCab's flight instrument displays for the 737-300 are shown in section 1.6.2.
Major differences between the M-Cab and a typical flight crew training simulator are listed below.

- The M-Cab can simulate different model airplanes including 707, 727, 737, 747, 757, 767, and 777.
- The M-Cab can be reprogrammed to simulate a wide variety of hypothetical aircraft system faults.
- The M-Cab can be "backdriven" to reproduce recorded data, such as the simulation match to the accident flight discussed in section 1.16.2. In addition, the backdrive can be interrupted at any point with a transition to normal simulator operation at the current flight conditions. This capability (known as "breakout" allows pilots in the simulator to attempt to recover the airplane from various points in the accident profile.
- The operation of the M-Cab is recorded at a high sample rate

The M-Cab was used to recreate the accident flight as well as to study a number of hypothetical airplane system faults.

Tests conducted in the M-Cab
The M-Cab was used to examine some of the faults mentioned in section 1.16.3, as well as a number of other hypothetical faults affecting the lateral control system or the autopilot system. M-Cab tests included:

- Backdrive of FDR data
- Backdrive with breakout at 02:44:44
- Backdrive with breakout at 02:44:56
- Spoiler float
- Uncommanded aileron trim to full authority
- Uncommanded aileron trim to half authority
- Autopilot servo actuator hardover without force limiter engaged
- Autopilot servo actuator hardover with force limiter engaged
- Autopilot servo actuator hardover with pressure regulator and relief valve inoperative

The tests in the M-Cab were conducted with an out-the-window scene equivalent to that available to the accident pilots with the following exceptions:

1) The visibility conditions simulated (ceiling and visibility unlimited at night with no moon) were those reported at the airport at the time of the accident. Actual visibility conditions on the flight deck at the time of the accident are unknown.
2) The ground in the vicinity of Sharm el-Sheikh was depicted through the use of satellite photography taken during daylight hours. It did not represent the nighttime scene of street lights, building lights, etc. against an otherwise dark landscape.

## Exhibit E

## Site and Wreckage Group Factual Report

## Site and Wreckage Group Report

## 1. Summary of the Accident

On 3 January 2004, Flash Airlines flight FSH604, a Boeing 737-300 registered as SU-ZCF, operating as a chartered flight from Sharm el-Sheikh, Egypt to Paris, France, via Cairo departed from Sharm el-Sheikh airport (SSH) at approximately 02:40 UTC. The airplane crashed into the Red Sea approximately 6 nautical miles southwest of the airport at approximately 02:44 UTC.

## 2. Scope of Site and Wreckage Group Field Notes

The scope of this report is the recovery operations that took place from 3 January 2004 through 28 January 2004 in the Red Sea off Sharm el-Sheikh, Egypt and initial inspection for the recovered parts. Recovery operations initially consisted of the recovery of floating wreckage elements only. Recovery of the underwater wreckage (including FDR and CVR) began when the first ship equipped with a suitable Remote Operated Vehicle (ROV), arrived at the accident scene on 11 January 2004.

This report provides a summary of the recovery operations and documents the wreckage that was identified and recovered.

## 3. Recovery Operations

### 3.1 Survival aspects

The initial search for possible survivors and the recovery of bodies were priorities for the rescue and investigation teams. Rescue teams were on site minutes after the accident. They searched for survivors but due to the high energy impact of the aircraft with the sea surface, the depth of the water in this area, their efforts were unsuccessful in recovering any survivors.

Efforts were made to locate human remains by use of deep sea cameras and robots but were also not successful due to the location of the wreckage and the depth of more than 1000 meters.

### 3.2 Floating Wreckage

The floating wreckage which was recovered shortly after the crash was stored in a hangar in Sharm el-Sheikh airport. On 11 January 2004, the Site and Recovery Group met in the hangar for wreckage inspection. The wreckage was then identified (as much as possible), inspected, segregated (aircraft parts or personal effects). Later, the personal effects were transferred to the Egyptian Legal Authority in Sharm el-Sheikh. A database for the floating wreckage was created (including wreckage pictures).

### 3.3 Underwater Wreckage

Because of the depth of the Red Sea in the area where the accident occurred (approximately 1000 meters), specialized recovery resources were required for the submerged wreckage. The French vessels "Ile de Batz" and "Janus II" were contracted to conduct the underwater wreckage survey and recovery. Both vessels were equipped with deep water recovery capabilities consisting of submersible Remotely Operated Vehicles (ROV). The necessary support equipment to accurately locate and map the airplane wreckage was provided by the French Navy. An oceanographic vessel, the "Beautemps-Beaupré" was sent to the accident site to undertake a bathymetry (depth mapping) of the seabed and a survey of tidal currents.

### 3.4 FDR I CVR Recovery

The initial focus of the underwater recovery operation was finding and retrieving the protected recorders, the Cockpit Voice Recorder (CVR) and Flight Data Recorder (FDR) and mapping the searched areas. Each recorder is equipped with an acoustic transmitter, called a "pinger" that transmits a detection signal that can be used to locate the box. Based on the initial determination of pinger locations, the ROV from Ile de- Batz, Scorpio, began a visual search using its cameras to find the recorders. To refine the location of the pingers, a network of sonobuoys (GIB, GPS Intelligent Buoys), (see Exhibit E Attachment 4 for detailed description of this operation), was employed in a cooperative effort between the French and Egyptian Navies. This method produced a new pinger position accurate to within 10 meters and the ROV was moved to the new location. A visual search of a grid created around the new pinger location resulted in discovery of the FDR on 16 January 2004. The FDR was recovered by the ROV and taken onboard the lle de Batz. Custody of the recorder was transferred to the Investigator in Charge (IIC) at the port of Sharm El Sheikh.

The pinger of the second recorder (CVR) was initially identified approximately 800 meters north of the first pinger. However, it was decided to continue the visual search using grids in the area where the first recorder was found. This search was successful and resulted in finding of the CVR on 17 January 2004 (approximately 24 hours after the FDR). It was also taken onboard the Ile de Batz and custody was transferred to the Investigator in Charge (IIC) at the port of Sharm El Sheikh.

FDR underwater Location: N27 52.3605, E34 22.0165.
CVR underwater Location: N27 52.3467, E34 22.0207.

The recorders were both sent to Cairo for read out and analysis.
The focus of the recovery operation then changed to detailed mapping of the wreckage and recovery of selected airplane equipment. In addition, the recovery operation included recovery of any equipment deemed important to the investigation based on the review of the FDR and CVR in Cairo.

### 3.5 Wreckage Mapping

During the structured search for the recorders, the position (latitude and longitude) and description of surveyed wreckage was recorded. Following recovery of the FDR and CVR, additional grids were defined for ROV operations. These grids were used to systematically survey and document the entire wreckage area. The positions of large pieces, such as the three landing gears and the cores of the two engines were identified.

Data from both ships involved in mapping and recovery were consolidated into a single listing of all surveyed wreckage, which is included herein as Exhibit E Attachment 5.

The distribution of wreckage is included within a rectangle of approximately 275 by 440 meters defined by the following corner point coordinates:

North corner: $\quad$ N $27^{\circ} 52,559 \mathrm{E} 34^{\circ} 21,933$
East corner: $\quad N 27^{\circ} 52,410$ E $34^{\circ} 22,126$
South corner: N 27º 52,294 E 34ㅇํ 22,022
West corner: N $27^{\circ} 52,450$ E $34^{\circ} 21,817$
Multiple surveys of the area confirmed the containment of the wreckage within these established boundaries.

### 3.6 Recovered Wreckage

The investigation team developed a strategy for wreckage recovery based on the review of the FDR and CVR undertaken in Cairo. Flight control actuation components and flight deck systems were considered as a priority.

A system was developed for recording the description, external dimensions and the location, in latitude and longitude coordinates, of all recovered wreckage pieces. A database of recovered floating wreckage is included herein as Exhibit E Attachment 5. Another database documenting all wreckage recovered by lle de Batz and Janus II is included as Exhibit E Attachment 5. Both databases reference digital images of all floating and recovered wreckage.

Recovered wreckage was stored aboard the ships in sea water until taken ashore and loaded onto trucks. All of the recovered wreckage is stored in a hangar at Sharm El Sheikh Airport and is under the control of the investigative authorities.

## 4. Partial list of the Recovered Wreckage

- Parts of the horizontal stabilizer central section structure (called "Texas Star"), elements of the elevator structure and components of the elevator control system, including both elevator PCU's (Power Control Unit), both autopilot actuators, the feel and centering unit including the feel actuator.
- Horizontal stabilizer jackscrew and actuator gearbox.
- Vertical stabilizer structure with rudder control system components, including the main rudder PCU and standby rudder PCU, the feel and centering mechanism and with the trim actuator.
- Aileron PCU, spoiler mixer and TBD spoiler actuators.

## 5. Initial observations

- The two engines were found approximately 24 meters apart
- The left and right main landing gear assemblies were found in between the two engines
- The recovered thrust reverser actuator was found retracted
- The recovered leading edge flap actuator was found retracted
- The recovered trailing edge flap jackscrew indicates that flaps were retracted
- The stabilizer jackscrew was measured at 7.5 inches between the flat of the ball nut and the flat of the end stop which corresponds to a stabilizer leading edge position between 2 and 3 degrees down or a trim unit setting between 5 and 6 pilot units. ${ }^{1}$

## 6. Wreckage Data bases and Photos

The full data base and photos of the wreckage are on a CD, which is available at the Egyptian Civil Aviation Ministry (MCA). This CD contains:
a. A folder with three Excel files for wreckage complete data base.
i. Floating Wreckage data base.
ii. Recovered Wreckage data base.
iii. Underwater Surveyed Wreckage data base.
b. A folder for photos with four sub-folders
i. Floating Wreckage Photos: 104 photos.
ii. Recovered Wreckage Photos: 98 photos.
iii. Underwater Surveyed Wreckage Photos: 330 photos.
iv. Wreckage Recovery Process Photos: 25 photos

Use of a GIB System For Recorders Recovery

## Use Of A GIB System For Recorders Recovery

A flight recorder immersed under water can be located by the signals (1 bip/second with $37,5 \mathrm{kHz}( \pm 1 \mathrm{kHz})$ ) transmitted by the ULB beacon (pinger) attached to the recorder. This pinger starts as soon as it is in contact with water and is designed to transmit this signal for at least thirty days.

The French Navy used an acoustic detector assembled on a pole called "Helle" which tracks signals on frequencies ranging from 7 to 50 kHz . This detector has two reception antennae, one omni-directional and the other directional. It was connected to an audio system that controlled the frequencies and was coupled with a GPS positioning system.

The first stage in the search consisted of checking signal transmissions and defining an general area using the omni-directional antenna. The seafloor being uncharted at that time, locating the beacons was complicated by possible reflections from the transmitted sound waves and possible secondary echoes. The next stage consisted of taking successive bearings using the directional antenna so to get a more precise fix.

This acoustic search determined two possible positions for the beacons: one to the south with a position considered as nominal since it could be picked up from all bearings, but which was transmitting more weakly than the one identified further north. The measurements and calculations performed gave an estimated depth of around one thousand meters.

To confirm these results, the USBL (ultra short base line - acoustic positioning) of the Ile de Batz (the first recovery ship on site) was later temporarily modified (in coordination with its manufacturer Sonardyne) and adapted to the reception of the signals transmitted by the southern pinger. These results confirmed the presence of a transmission source beneath the Ile de Batz which had been positioned directly above the estimated position.

To narrow the search area, the French Navy contracted ACSA to supply a GIB system (GPS Intelligent Buoys). They adapted a network of four acoustic receivers, combined with GPS information, to conduct a search at a depth of around one thousand meters .

The hydrophones, immersed 450 meters down around the initial identified position, drifted with the current while permanently transmitting information on their position and any signals received. An algorithm integrated all data to determine the recorder's fixed position.

The ROV started searching for the recorders using its cameras based on an initial determination of the position of its beacon. This position was then refined by the ACSA system. That produced a theoretical position with a precision of plus or minus ten meters over one hundred meters.

Squares of twenty by twenty meters were systematically searched by the ROV.

The FDR was discovered on $16^{\text {th }}$ January 2004 approximately twelve meters from the computed position.

On the basis of the initial analysis of wreckage distribution, it was decided to define a zone to the south of the position of the FDR. The CVR was found on $17^{\text {th }}$ January 2004 in a nearby traced square.

## OPERATIONS

## 1. ACCIDENT

| Operator: | Flash Airlines |
| :--- | :--- |
| Location: | Sharm-El-Sheikh, Egypt |
| Date: | January 3. 2004 |
| Time: | 0246 UTC |
| Airplane: | Boeing B-737-300, SU-ZCF, Serial Number 26283 |

## 2. SUMMARY

On January 3, 2004, about 02:45:06 UTC, 04:45:06 Local time, Flash Airlines flight FSH604, a Boeing 737-300, Egyptian registration SU-ZCF, crashed into the Red Sea shortly after takeoff from Sharm el-Sheikh International Airport (SSH) in South Sinai, Egypt. The flight was a passenger charter flight to Charles de Gaulle Airport (CDG), France with a stopover in Cairo international Airport (CAI) for refueling. Flight 604 departed from Sharm el-Sheikh airport with 2 pilots (Captain and First Officer), 1 observer, 4 cabin crew, 6 offduty crew members and 135 passengers on board. The airplane was destroyed due to impact forces with the Red Sea with no survivals.

The airplane had departed from Sharm el-Sheikh runway 22R and was air born at 02:42:33 UTC, approximately $21 / 2$ minutes prior to the crash, and had been cleared for a climbing left turn intercept the 306 radial from the Sharm el-Sheikh VOR station located just north of runway 22R. This climbing turn allows departing flights to gain sufficient altitude before proceeding over higher terrain located along the flight path to Cairo. Flight 604 was operating in Egyptian airspace as a charter flight operating under the provisions of Egyptian Civil Aviation Regulations Part 121

## 3. DETAILS OF THE INVESTIGATION

The Operations group convened at 1100 on January 14, 2004 at the offices of the Ministry of Civil Aviation. An interview was conducted with the Chief Pilot of Flash Airlines regarding the pilot and co-pilot qualifications. Pilot training records were reviewed and information was collected to include medical and flying licenses and total flying time. A member of the operations group participated in the interview of the ground engineer that flew

[^21]on the airplane prior to the accident flight. A review of the weight and balance of the flight was conducted. Activities were concluded on January 22, 2003.

### 3.1 AIRPORT INFORMATION

According to the Aeronautical Information Publication (AIP), Sharm El Sheikh International Airport was located 23 kilometers northeast of the city. The elevation of the airport was 143 feet mean sea level. The airport had two paved parallel runways; 04L-22R and 04R-22L. Both runways were 3081 meters in length and 45 meters in width. Runways 04R and 04L had CAT 1 Approach Lighting System and runways 22R and 22L had Simple Approach Lighting System. Neither runway had runway centerline lights.

According the AIP Flight procedures, there was no standard departures and standard arrival routes or any other systematic procedures established within. Sharm El Sheikh approach airspace, heading, flight level, speed and or holding instructions shall be specified in approach control clearances to arriving and departing flights as appropriate to meet the requirements of traffic conditions.

### 3.2 FLIGHT CREW INFORMATION

Both flight crewmembers were certificated under Egyptian Civil Aviation Supervisory Sector Authority (ECASSA).

### 3.2.1 Captain Khedr Abdalla Saad Said

- Date of birth:
- Date of hire with Flash Airlines:

February 26, 1950
February 16, 2003

- Airline Transport Pilot Egyptian Certificate Number 561 (issued December 15, 1984)
o Airplane Multiengine Land
o Airplane Single Engine Land/Commercial Pilot
- Limitations: None
- Type Ratings:ATR-42, B-737/300/400/500 (issued May 27, 2003), DHC-5 Buffalo, C130, Gomhorya.
- Medical: First Class (issued November 19, 2003)
- Limitations: None
- Initial Ground School Training:
o Written Test: April 9, 2003
o Oral Test: May 22, 2003

Total flying Time 90 days: 61:10

### 3.3 WEIGHT AND BALANCE

The Flash Airlines weight and balance calculations provided to the flight crew contained the following information ${ }^{6}$ :

|  | Weight <br> (kilograms) |
| :--- | :--- |
| Total Traffic Load | $11,450^{7}$ |
| Dry Operating Mass | 33,200 |
| Actual Zero Fuel Mass | 44,650 |
| Maximum Zero Fuel Mass | 47,627 |
| Takeoff Fuel | 7,000 |
| Actual Takeoff Mass | 51,650 |
| Maximum Takeoff Mass (Certificate Limit) | 63,276 |
| Landing Mass | 49,650 |
| Maximum Landing Mass (Certificate Limit) | 51,709 |

| Zero Fuel Mass Center of Gravity (CG) | $20.0 \%$ |  |
| :--- | :--- | :--- |
| Zero Fuel Mass CG Limits $^{8}$ | $8.0 \%$ Forward | $28.4 \% \mathrm{Aft}$ |
| Takeoff Mass CG $^{\text {Takeoff Mass CG Limits }}{ }^{9}$ | $18.0 \%$ |  |
| Ta. | $6.7 \%$ Forward | $27.9 \% \mathrm{Aft}$ |

[^23]- Stabilizer Trim settings for takeoff were:

| Flaps 1 or 5 | $43 / 4$ Units |
| :--- | :--- |
| Flaps 15 | $33 / 4$ Units |

- According to the Flash Airlines Flight Operations Manual Chapter 6, Paragraph 6.1.8.3, Passenger and Baggage Masses, the following chart was published:

|  | Male | Female |
| :---: | :---: | :---: |
| All flights except | 88 kg | 70 kg |
| Holiday | 83 kg | 69 kg |
| Children | 35 kg | 35 kg |

- A review of the accident aircraft Load and Trim Sheet indicated a Passenger Mass of $9,450 \mathrm{~kg}$. If 350 kg is removed for 10 children ( 10 x 35 kg ) the result is $9,100 \mathrm{~kg}$. Dividing the 125 adult passengers into the $9,100 \mathrm{~kg}$ would give an average value of 72.8 kg per adult passenger.
- Using the table above, and assuming 50\% Male and 50\% Female adult passengers, the worst-case difference in weight calculation would be the following:
o The average weight of male and female for all flights except would be $88 \mathrm{~kg}+$ $70 \mathrm{~kg} / 2=79 \mathrm{~kg}$ per adult passenger.
o 79 kg x 125 passengers $=9,875 \mathrm{~kg}$
o The represents an increase in weight of 775 kg .
o Using this value for Load and Trim calculations provided the following information:
- Takeoff CG
18.2\%MAC
- Zero Fuel Mass CG

20\% MAC

- Takeoff Trim (flaps 5) $43 / 4$ Units
- These worst-case differences in values for passenger weight still fall within structural and calculated limitations for the airplane.

### 3.4 AIR TRAFFIC CONTROL

An Interview with the Director of Radar Airports, National Air Navigation Service Company indicated that at SSH, the local controller and the departure controller were the same person. The previous last flight departure before the accident flight departed about one hour earlier. An arrival flight landed less than 10 minutes after the accident flight departed. Radar was operating but no radar service was provided to the accident flight.

According to the Director, there were no Standard Instrument Departures (SIDs), or Standard Terminal Arrival Routes (STARs) in Egypt. Clearance was provided to the accident flight crew while on the ground and the departure included a left turn at pilot's discretion and to climb to Flight Level (FL) 140 overhead the SSH VOR/DME and to intercept the airway A411 ${ }^{10}$. The minimum crossing altitude for ATC purposes was 4,000 feet, however, pilots prefer to cross at or above 10,000 feet.

[^24]According to the Director, the prevailing winds at SSH require the use of runway 04L $70 \%-80 \%$ of the year. On the date of the accident, runway 04 L was being used. However, sometime during the day prior to the accident, the runway was changed to 22R.

There was not an inspection of the runway after notification of the accident, however, it was stated that the landing airplane after the accident did not report debris on the runway. There is a daily runway inspection performed at SSH.

### 3.5 METEROLOGY

Sharm El-Sheikh does not provide Automatic Terminal Information Service (ATIS).

The SSH weather at 0200Z was reported as:
270 degrees at 06 knots, Ceiling and visibility OK (CAVOK) temperature 17 degrees Celsius, dewpoint minus 6 degree Celsius, altimeter 1011 hectoPascals (hPa), No significant change (NOSIG). ${ }^{11}$

The SSH weather at 0300 Z was reported as:
280 degrees at 08 knots, Ceiling and visibility OK (CAVOK) temperature 17 degrees Celsius, dewpoint minus 6 degree Celsius, altimeter 1011 hectoPascals (hPa), No significant change (NOSIG).

[^25]
### 2.0 ANALYSIS

### 2.1 Analysis Overview

## Methodology used:

During the investigation, the accident investigative team, which consisted of Egyptian, French, and U.S. investigators, mutually agreed upon and adopted a "scenario tree" methodology to determine the accident sequence of events.

As part of this methodology, the investigative team identified possible accident scenarios, and sufficient evidence existed for the team to rule out the inapplicable scenarios.

The team then examined the remaining scenarios and the evidence collected during the investigation to determine which scenario most likely explained the accident sequence of events.
This Fault Tree Methodology has been applied for both:

- Technical related issues
- Human Factors related issues

Fault Tree Methodology Breakdown:

1) Define Accident Top Event

- Gather Performance, Data Recorders, and Operational Factors Investigators to brainstorm
- Layout all known evidence and facts related to
- Develop Sequence of Events if timing of events is known
- Decide on a description of what went wrong with the aircraft

2) Determine Most Direct Causes
3) Continue Breaking Down Causes
4) Use Facts to Draw Conclusions
5) Define Probable Cause Path

## Overview:

The analysis Chapter addresses the following issues:

## - Airplane Performance Evaluation

The performance evaluation was intended to study the behavior of the flight control surfaces as related to the inputs to the flight controls, and the airplane behavior as related to the movement of the control surfaces.

In order to accomplish this work, Boeing's 737-300 aerodynamic simulation model was used to recreate the accident flight based on the data recorded in the FDR.

A simulation procedure was used to calculate the response of the airplane to movement of the flight control surfaces.
Small differences between the simulation and individual airplane's behavior are common and expected due to differences in control surface rigging, engine wear, and other normal tolerances.

A Kinematic consistency (KINCON) process was used to supplement the FDR data and calculate additional parameters to be used in the performance analysis.

Information from the airplane performance model, wind tunnel data, flight test data, control surface models, propulsion model, autopilot model, etc, were used.

A baseline simulation recreation of the accident flight was started just as the airplane turned on to the runway and the throttles were advanced, and the simulation was stopped at the end of the FDR data.

An examination of the baseline simulation revealed that the path of the accident airplane is consistent with the recorded motion of the control surfaces. Specifically, the extreme bank attitude that occurs towards the end of the flight is consistent with recorded motion of the ailerons.

A sensitivity analysis was made for one of the airplane parameters (pressure altitude). The analysis showed that the M - Cab computed parameters are quite sensitive to the values of the used input parameters, for example an amount of 65 lb change in the airplane weight would result in a change of the computed altitude by an amount of 200 ft

Weight and Balance data were analyzed. Analysis revealed a normal airplane loading with correct computations of the airplane weight, c.g. location, stabilizer setting and the Take Off speeds V1, VR, V2.

Radar data was analyzed. An examination of the Radar data and the FDR data revealed that the path of the accident airplane as derived from the Radar data is consistent with the it's path as derived from the FDR date

- Analysis of Airplane systems behavior:

All the airplane systems parameters have been thoroughly examined. All parameters were plotted against time. In several cases, several parameters were plotted together whenever needed to support the investigation. It was noted that several parameters had invalid data.
All the systems were examined to check there behavior through the flight.

The M-Cab was used to derive some of the missing data (including the control wheel position). The remaining invalid data did not inhibit the investigation

- Main events in Chronological sequence

For the sake of the analysis, all the main events were listed in a chronological sequence. These events were used with the fault tree analysis.

- Analysis of the main events

The methodoly adopted by the investigation team for the analysis was as follows:

- To collect all pertinent information from the available sources (FDR, CVR, records, manuals, questionaires, etc) and process this data as required.
- To list and encode the Main events in Chronological sequence
- To use the facilities associated with the fault tree analysis technique to analyse each individual event.
- To list all the possible causes and hypothetical conditions leading to each individual event.
- To rule out all the conditions which seem not pertinent to the event based on systems and human Factors reviews and consider the remaining conditions.
- To review all the other remaining conditions from the point of view of the systems and the human factors analysis
- Listing the Pros (issues that support the probabilty of condition occurrence) and Cons (issues that do not support the probabilty of condition occurrence) related to each condition
- Determining the most probable cause (s) for each individual events

After several meeting of the investigation team held in:

- Cairo January 2004
- Cairo March 2004
- Paris May 2004
- Seattle September 2004
- Cairo February 2005
- Cairo August 2005

Two studies have been developed by the whole investigation team jointly addressing both the:

- Systems analysis (fault tree)
- Crew behavior

The contents of the study related to the "Systems analysis (fault tree)" is shown in section 2.5

See section "2.6 Crew Behavior", Thread Overview Updates Cairo 26-Aug05, Flash Air CBS Sub-group Comments (25 August 2005)"

### 2.2 Airplane Performance Evaluation:

### 2.2.1. General

The performance evaluation was intended to study the behavior of the flight control surfaces as related to the inputs to the flight controls, and the airplane behavior as related to the movement of the control surfaces.

In order to accomplish this work, Boeing's 737-300 aerodynamic simulation model was used to recreate the accident flight based on the data recorded in the FDR.

FDR relevant parameters:
Several parameters were recorded in the FDR (related to the aircraft performance including):

- The movements of the pilot's controls:
- Control column
- Control wheel position (FDR data is not reliable)
- Rudder pedals
- Speed brake handle
- The movement of the primary control surfaces:
- Elevators
- Ailerons
- Rudder
- Stabilizers
- The movement of the secondary control surfaces:
- T.E. Flaps
- L.E. Devices (flaps, slats)
- Motion of the airplane:
- Pitch
- Angle of attack
- Roll attitude
- Heading angle
- Drift angle
- Airplane acceleration
- Vertical
- Longitudinal
- Lateral
- Additional parameters, including:
- Airplane pressure altitude
- Radio height
- Computed airspeed
- Barro corrections
- Ground speed
- Total Air Temp
- Gross weight
- Wind speed
- Wind direction
- Stick shaker condition
- Present position Lat
- Present position Long

### 2.2.2 Simulation procedure:

The simulation calculates the response of the airplane to movement of the flight control surfaces - for example, it can calculate the roll rate resulting from a 10 degree deflection of the ailerons. The simulation has been verified by comparison against actual flight test data and was used for the design and certification of the 737-300 airplane. In addition, the simulation is the basis for 737-300 crew training simulators used around the world.

However, and because the 737-300 simulation model is essentially a computer program that represents a nominal airplane with nominal engines, small differences between the simulation and individual airplane's behavior are common and expected due to differences in control surface rigging, engine wear, and other normal tolerances.

FDR data are recorded at relatively low sample rates (most of the parameters are recorded each one seconds) and are recorded from different sources, some of which have inherent biases. Because of these issues, a Kinematic consistency (KINCON) process was used to supplement the FDR data and calculate additional parameters to be used in the performance analysis. Kinematic consistency analysis is a general practice for processing flight data (either flight test data or FDR data) to ensure consistency of position, speed, and acceleration data.

The KINCON Process independent of control surface inputs, it also performs the following:

- Removes constant biases from FDR accelerations
- Ensures corrected acceleration data are consistent with FDR ground speed, drift angle, and altitude
- Can derive parameters not recorded
- Provides calculated parameters with higher sample rates than FDR parameters

Kinematic consistence (KINCON) also models the accelerations and Euler angles as smooth functions which allows more accurate calculation of derivatives

The Kinematic consistency process does not make any assumptions about the aerodynamic properties of the airplane. In fact, the process can be applied to any moving object

Based on the airplane performance model, wind tunnel data, flight test data, control surface models, propulsion model, autopilot model, etc, the primary performance parameters can be derived at time $t_{1}$ based on their values at time $t_{0}$. These primary performance parameters include:

- Column
- Wheel
- Pedal
- Pitch
- Roll
- Heading
- Stab
- Thrust
- Flaps
- Gear
- Altitude
- Airspeed

The resulting simulation data can be separated into different categories

1. Math pilot - not calculated using corresponding FDR data for the main primary control inputs (Column, Wheel and Pedal)
2. Kincon Output - kinematically consistent path data (accelerations and angles) for the airplane Euler's angles (Pitch, Roll, Heading)
3. Pass Through Data- FDR data is used directly as an input to simulation for the following parameters

- Stab
- Thrust
- Flaps
- Gear

In some cases, a correction is added to improve the simulation match of the path (thrust may be added to better match airspeed)

For Flash Airlines simulation the stabilizer was adjusted to account for control column bias ( $2.9^{\circ}$ offset), and the throttle lever position was adjusted to improve match of airspeed and altitude
4. Simulator Output - not calculated using corresponding FDR data, but is a direct result of the aero model for parameters like Altitude and airspeed

Pass Through Data:
For Flash Airlines simulation:

- Stabilizer was adjusted to account for control column bias ( $2.9^{\circ}$ offset)
- Throttle lever position was adjusted to improve match of airspeed and altitude

A baseline simulation recreation of the accident flight was started just as the airplane turned onto the runway and the throttles were advanced, and the simulation was stopped at the end of the FDR data. Because the simulation can calculate the response of the airplane to control inputs, a set of control input time histories (column, wheel, and rudder movements) were determined that results in the simulation following the same path as the accident airplane. It is important to note that this process does not use the control or surface position data recorded on the FDR, only the path information (e.g. accelerations, attitude and altitude).

Comparisons between the recorded FDR data and the simulation time history data are provided for longitudinal and lateral/directional data in Figure 1.16.2-1 and Figure 1.16.2-2 respectively.

Figure 1.16.2-1 - FDR and Simulation Match Data - Longitudinal Axis

Figure 1.16.2-2 - FDR and Simulation Match Data - Lateral/Directional Axis

An examination of the baseline simulation revealed that the path of the accident airplane is consistent with the recorded motion of the control surfaces. Specifically, the extreme bank attitude that occurs towards the end of the flight is consistent with recorded motion of the ailerons.

## Conclusion (Simulation):

Based on the simulation data, the motion of the control surfaces showed consistency with the recorded motion of the control inputs, with the exception of control wheel (because of the unreliable recorded control wheel data)
(See also the conclusion of the sensitivity analysis)

### 2.2.3 Sensitivity analysis:

Accident flight is approximately 147 seconds long; simulator match of altitude differs by approximately 200 feet (refer to Fig xx Pressure Altitude vs time frames, FDR and Simulation data)

A sensitivity analysis for straight and level flight 147 seconds long was made to determine how much the altitude can be affected by the lift force on the airplane Using Newton 2nd law relating the vertical forces to vertical acceleration and then integrating to get the height $z$ we get

$$
\begin{aligned}
& \mathrm{F}=\mathrm{M}^{*} \mathrm{~A} \\
& \mathrm{~F}=\mathrm{L}-\mathrm{W} \\
& \ddot{z}=\frac{L-W}{W} \\
& \mathrm{z}=\iint \frac{L-W}{W} d t^{2}
\end{aligned}
$$

For constant weight

$$
z=\left.g \frac{L-W}{W} \frac{t^{2}}{2}\right|_{t_{1}} ^{t_{2}}
$$

Assume altitude error is result of incorrect lift

$$
\Delta z=g \Delta \frac{L-W}{W} \frac{t^{2}}{2}
$$

Solve for $\Delta \mathrm{L}$

$$
\Delta L=\frac{2 W \Delta z}{g t^{2}}
$$

By substitution, it can be noted that
A 65 lb error in calculated lift will result in an altitude error of 200 ft after 147 seconds.
(Refer to section 1.16.1.0 Tests and researches conducted by Boeing and Honeywell, Kinematic Consistency)

Fig 2.2.3.1 Pressure Altitude vs time frames (FDR and Simulation data)

## Conclusion (Sensitivity analysis):

The results obtained from the M -Cab tests indicate that the computed parameters are quite sensitive to the values of the used input parameters, for example an amount of 65 lb change in the airplane weight would result in a change of the computed altitude by an amount of $200 \mathrm{ft}^{1}$

[^26]
### 2.2.4 Weight and Balance ${ }^{2}$

Although the average weight for passenger used in Load and Trim sheet for the Weight and Balance calculation was not the one given in the airline Flight Operations Manual, none of the available data relevant to the airplane weight and balance showed evidences of airplane loading abnormality. Computations of the airplane weight, c.g. location, stabilizer setting and the Take Off speeds V1, VR, V2 were correct.

[^27]
### 2.2.5 Analysis of Radar data: ${ }^{3}$

In the following Figures the aircraft path (indicated by Lat-Long and $x-y$ coordinates) based on radar data is shown

Figure C.2-1 Radar Data Plot, Sharm El Sheik Radar

[^28]

Fig C.2-1a Coordinates (Derived from Radar Data)
(Latitude and longitude coordinates, are transformed into this coordinate system using the WGS84 ellipsoid model of the Earth).

It is noted that the time scale of the radar is not exactly in match with the time scale of FDR. Based on the FDR timing, the airplane crashed in the water at 02:45:06 GMT (92480), while the radar indicated airplane disappearance at 02:47:27 GMT (about 141 seconds later). The last radar return from the airplane which can be considered as reliable was at 02:46:39 Radar time (about 92467 second frames on
the FDR data based on the altitude data). The airplane altitude shown was 4600 ft . The radar data did not show any further smaller altitudes.
The letter n was shown on the Radar data starting from 02:46:47 radar time (about 92475 second frames on the FDR)
The letter n indicates that mode C altitude has not been updated for approximately 7.5 seconds and is considered unreliable, aircraft is below adapted transition level and altitude is in hundreds of feet above mean sea level

## Conclusion (Radar data):

An examination of the radar data and the FDR data showed that the path of the accident airplane as derived from the radar data is consistent with the path as derived from the FDR date

### 2.3 Analysis of Airplane systems behavior:

### 2.3.1 Environmental Control System (ECS)

The FDR records some parameter related to ECS including:

- ECS packs status (On/ Off, Low/ High)
- Isolation valve poaition (Closed/ Open)
- Cabin pressure altitude (if higher than 10,000 ft)

Based on FDR data and CVR recorded information, there is no evidence of ECS system failure or abnormal behavior. Thus, the ECS system does not have any relation with the accident.
2.3.2 Fire

The FDR monitors the following for conditions of fire:

- Engine 1 and 2
- APU
- Wheel well
- Lavatory (monitors for smoke)

Based on FDR data and CVR recorded information, there is no evidence of any fire condition in the engines, APU, the lavatories nor the wheel well..
2.3.3 Flight controls

The Following parameters were recorded in the FDR
:Analog Data:

- Ailerons positions (Degrees)
- Elevators position (Degrees)
- Pitch Trim position (Degrees)
- Rudder position (Degrees)
- TE Flaps position (Degrees)
- Control wheel position (Degrees)
- Control Column position (Degrees)
- Rudder Pedal position (Degrees)
- Speed Brake Handle position (Degrees)
- Discrete Data
- Alternate Flaps switch position
- L.E Flaps \# 1,2,3,4 status (Extend, In Transit)
- L.E Slats \# 1,2,3,4,5,6 status (Full Extend, In Transit, Mid Extend)

Close observation of the flight controls parameters showed the following:

- Some parameters values were unreliable
- Aileron control wheel
- Slat \# 1 (showed mid extend position from the very beginning)
- The two ailerons shows a bias of about one degree TEU (Trailing Edge Up) before airborn. After airborn, the bias changed to about 2.7 degrees. (The changes in aileron position bias could be caused by the Airload on the aileron reacting against the wing cable run between the aileron and aileron PCU. Therefore, the bias in aileron position is due to aileron hinge moment which varies as a function of airspeed).
- The Pitch trim reading indicated a constant bias from the expected trim position. This bias was corrected in the M- Cab tests.
- Because the spoiler surface positions are not recoreded in the FDR, any possible abmormality with the spoiler surfaces data can not be shown by the FDR.
- For the consistency analysis between the airplane behavior and the flight control surfaces, See section 2.2 Airplane Performance evaluation.
- A full analysis of the aircraft lateral control system has been done (refer to appendix 2-1 lateral control analysis). All the hypothetical failures in the system have been comprehensively studied All the scenarios resulting from each individual failure (or combination of particular failures) were checked against the accident scenario. Most of the hypothetical failures scenarios were ruled out because of there inconsistency with the accident scenario. The remaining hypothetical scenarios were further examined because they could not be excluded based on a review of FDR data. These hypothetical failures scenarios are as follows ${ }^{1}$ :
- Both trim switches are stuck closed in the same direction:
- Autopilot actuator, both Solenoids and Transfer Valve Jammed (Actuator Hardover without Force Limiter 17 to 20 lb Force)
- (Spoiler wing cable jam) offset of the neutral position at time 92450 (maximum wheel deflection). and clears at 92472
- (F/O wheel jam) offset of the neutral position at time 92450 (maximum wheel deflection).and clears at 92472
2.3.4 Fuel system:

The Total Fuel Mass is the only parameter recorded in the FDR. It is sampled each 64 seconds. Only three samples were recorded as follows:

Time (seconds) Total Fuel Quantity (KGS)
92304
6404.732

[^29]The amounts of fuel in each individual tank are not recorded in the FDR. Thus the FDR fuel information does not identify any condition of fuel assymetry (if any)

The fuel mass as recorded in the Load Sheet was 7000 kg . It is noted that the FDR showed some slight increase in the Total Fuel Quantity between 92304 and 92368 (about 450 Kg ). Change of airplane attitude and the airplane acceleration could explain these abnormal changes.

However, the available information indicates that the fuel system did not have any relation with the accident

### 2.3.5 Hydraulic system

The FDR records some parameter related to Hydraulics including:

- Systems pressure (system A and system B)
- Hydraulic pumps output pressure status (A hydraulic pumps, B hydraulic pumps, standby pump)
(Sample rate is 64 seconds)
Close observation of the hydraulics parameters showed the following:
- The System pressure recorded for both system A and system B were unreliable (press values were above 5000 psi)
- Hydraulic pumps output pressure status (A hydraulic pumps, B hydraulic pumps, standby pump) showed "No Low Press" status
- Sys A hydraulic loads (Landing Gears, T.E. flaps. L.E. Devices) were driven to the commanded positions.
- Flight control surfaces (powered by A and B systems) showed several movements through out the whole flight.

Based on the FDR available date, there is no evidence that the hydraulic systems do not have any relation with the accident.

### 2.3.6 Landing Gears

The Following parameters were recorded in the FDR (Sampling rate was each one second)

- Brake Press (Left, Right)
- Gear Position (Nose, L main, R main)
- Gear Red Warning Light (Nose, L main, R main)
- Air/ Ground (Main, Nose)
- Wheel Well Fire
- Main/ Alt Brake Switch

Close observation of the engines parameters showed the following:

- Wheel Well Fire recording is unreliable (always changing between Fire and No-Fire status)
- Gear Red Warning Light (Nose, L main, R main) showed red warning at the time of retarding the throttles levers. This condition could be normal with Landing Gears in the up position.

Based on the FDR available date, there is no evidence that the landing gears have any relation with the accident.

### 2.3.7 Power plants

The FDR records the following parameters for both engines:

- N1 (\%RPM)
- N2 (\%RPM)
- FUEL FLOW
- THRUST LEVER ANGLE
- ENG OIL PRESSURE
- ENG OIL QUANTITY
- OIL TEMP
- ENGINES CUTOFF LEVER Position Status
- ENGINES FIRE Status
- ENGINES T/R L, R SLEEVE DEPLOYED Status
- ENGINES T/R L, R SLEEVE NOT STWD Status
- CN1 (Low Press Compressor) TRACKED VIB
- CN2 (High Press Compressor) TRACKED VIB
- TN1 (Low Press Turbine) TRACKED VIB
- TN2 (High Press Turbine) ACCEL SRC
- FAN IMB ANGLE
- COWL ANTI ICE Status
- ENGINE BLEED Status
- PMC (Power Management Computer) Status
- GO AROUND N1 (\%RPM)
- MAX CONTINUOUS N1 LIMIT (\%RPM)
- MAX CLIMB N1 LIMIT (\%RPM)
- MAX CRUISE N1 LIMIT (\%RPM)
- N1 BUG DRIVE (\%RPM)
- TARGET N1 (\%RPM)

Close observation of the engines parameters showed the following:

- Some parameters values were unreliable
- CRUISE N1 LIMIT \#2
- N1 L
- ENG 1 CUTOFF lever position
- ENG 2 CUTOFF lever position
- All T/R Sleeves Showed stowed and locked position
- Engine bleeds were on
- Based on N2 comparison for both engines, the two engines showed symmetrical thrust
- Engines power were reduced at about 92472 timeframe (seconds) (consistent with CVR announcements) The left engine PLA data indicated slight throttle lever advancement at 92477 ending at 92479
- Both PMC's (Power Management Computer) were On.
- Fire discrete parameters indicated "No Fire" in the engines

Based on the FDR available date, there is no evidence that the engines have any relation with the accident.

### 2.3.8 APU

Only the APU FIRE status was recorded in the FDR
Based on the FDR available date, there is no evidence that the APU has any relation with the accident.
2.3.9 Auto Flight \& Communication:

The Following parameters were recorded in the FDR (Sampling rate was each one second in most cases):

Analog Parameters:

- DH SEL (FEET)
- DISTANCE TO GO (NM)
- DME DISTANCE L (NM)
- DME DISTANCE R (NM)
- G/S DEV EFIS (DDM)
- LOC DEV EFIS (DDM)
- SEL AIRSPD FCC L (KNOTS)
- SEL ALT FCC L (FEET)
- SEL COURSE 1 (DEG)
- SEL COURSE 2 (DEG)
- SEL HEADING FCC L (DEG)
- SEL MACH FCC L (MACH)
- VOR/ILS FREQ L (MHz)
- VOR/ILS FREQ R (MHz)

Discrete parameters

- Range Selection Status (Captain, F/O)
- A/P Off Status
- A/P Warning Status
- A/T Engage Status
- A/T GA Status
- A/T Limit Status
- A/T Manual Disconnect Status
- A/T MCP Speed Engagement Status
- A/T MIN Speed Engagement Status
- A/T N1 Engagement Status
- A/T Retard Engagement Status
- A/T Warning Status
- AIRPORTS Select Status (Captain, F/O)
- ALT ACQ FCC Engagement Status
- ALT HOLD FCC Engagement Status
- APPROACH FCC Engagement Status
- CMD A FCC Engagement Status
- CMD B FCC Engagement Status
- CWS A FCC Engagement Status
- CWS ROLFCC L Engagement Status
- DONT SINK Status
- EFIS /NON EFIS Selection
- EFIS SEL SW CAPT Status
- EIS /NON EIS Status
- EVENT MARKER Status
- F/D A ON FCC Status
- F/D B ON FCC Status
- FLARE ENGA FCC (0-. 1-ENGA)
- FMC SEL SW Status (Captain)
- FMC/IRU DATA SOURCE Selection(0-IRU 1-FMC)
- FULL COMPASS ROSE Selection (Captain, F/O)
- G/S ENGA FCC Engagement Status
- G/S GPWS Status
- HDG SEFCC L Engagement Status
- HF KEYING Selection (Left, Right)
- ILS (MOD) Selection (Captain, F/O)
- ILS (STD) Selection (Captain, F/O)
- INNER MARKER Status
- IRS SEL SW Selection (Captain)
- L NAV ENGA FCC Engagement Status
- LEVEL CHANGE FCC Engagement Status
- LOCAL LIMITED MASTER Setting Status
- MAP MD SEL Status (Captain, F/O)
- MASTER CAUTION Status.
- MCP SPEED FCC Engagement Status
- MIDDLE MARKER Status
- MINIMUMS Status
- MLS SEL (Left and Right) Selection
- NAV AIDS Selection Status (Captain, F/O)
- NAV MODE SEL Status (Captain, F/O)
- OUTER MARKER Status
- PLAN MD SEL Status (Captain, F/O)
- PULL UP Status
- ROUTE DATA SEL (Captain, F/O)
- SCAN DME / NON SCAN DME Status
- SINGLE CHANNEL FCC L Engagement Status
- SINK RATE Status (0-. 1-TRUE)
- STICK SHAKER Status (Left and Right)
- TERRAIN Status
- TERRAIN PULL UP Status
- TO/GA FCC Engagement Status
- TOO LOW FLAP Status
- TOO LOW GEAR Status
- TOO LOW TERRAIN Status
- TRIM DN A/P Trim Status
- TRIM DN MAN Trim Status
- TRIM UP A/P Trim Status
- TRIM UP MAN Trim Status
- TRUE / MAG SW Selection Status
- VIS MODE FCC Engagement Status
- VHF C KEYING Status (Left, Center, Right)
- VOR (STD) SEL Status (Captain, F/O)
- VOR MD SEL Status (Captain, F/O)
- VOR/ILS SEL Status (Left, Right)
- VOR/LOC ENGA FCC Engagement Status
- WAY POINT SEL Status (Captain, F/O)
- WINDSHEAR Status
- WINDSHEAR CAUTION Status
- WXR DATA Selection Status (Captain, F/O)
- YAW DAMPER DISENGAGE Status
- A/P OFF FCC Status
- A/P WARNING Status
- CMD A FCC Engagement Status
- CMD B FCC Engagement Status
- CWS A FCC Engagement Status
- CWS ROLL FCC L Engagement Status
- HDG SEL FCC Left Engagement Status

Close observation of the Autoflight Systems showed the following:

- A/P OFF FCC status showed ON condition at 92413 and then OFF Condition at 92416
- CMD A FCC Status showed an engagement condition at 92413 and then disengagement at 92416
- A/P WARN status showed warning condition at 92416, the warning ended at 92417
- A/T ENGA showed engagement status throughout the flight.
- A/T MAN DISC showed no manual disconnection
- A/T N1 showed disengagement condition up to 92295, then A/T N1 showed engagement condition up to 92308. A/T N1 remained disengaged in the interval between 92309 and 92355, after that A/T N1 remained Engaged.
- CWS ROLL FCC L showed engagement condition at 92413, then disengagement at 92416
- FD A ON FCC, FD B ON FCC showed ON condition throughout the whole flight.
- HDG SEL FCC L showed engagement condition at 92341 up to 92413. HDG SEL FCC L was disengaged at 92414 up to 92421 . After that it remained engaged till the end of the flight
- LEVEL CHANGE FCC showed engagement status at 92344. Engagement condition remained till the end of the flight
- Course selected was 306 (sampled every 64 seconds)
- Heading selected was $\sim 360$ degree (at 92323 ) followed by $\sim 107$ degree (at 92387 ) then $\sim 85$ degrees (at 92451). Heading was sampled every 64 seconds.
- VOR selection was 114.2 MHz
- MCP SPEED FCC showed engagement condition at 92344. Engagement condition remained till the end of the flight
- TOGA FCC showed an engagement condition only for 2 seconds (92296, 92297)
- WINDSHEAR and WINDSHEAR CAUTN did not show any condition of Windshear.

Full analysis of the main events related to Auto Flight Systems has been carried out. (See section 2.5. Anaysis of the chronological main events.)
2.3.10 Miscellaneous:

- Master Warning

FDR data Showed "Master Warning On" status at 92465
Conditions resulting in Master Warning condition are indicated in the following table:

## Master Caution Discrete at Time 92465

All the above conditions can result in Master Caution activation. Based on the available data, it is hard to identify one individual fault as the cause of this event.

### 2.4 Main events in Chronological sequence

Based on the information collected from the FDR and the CVR, a sequence of the main events that occurred during the accident flight has been established. These main events are:
1.0 TO/GA Mode Disengage
2.0 Aileron Movement during Take Off
3.0 FD Modes (Pitch-Roll Re-engagement
4.0 Roll Left, and Left Turn Begun
5.0 Roll Back towatrds Wing Level
6.0 Pitch Up and Airspeed Decay
7.0 Autopilot Engage Sequence
8.0 Mode Change from "HDG SEL" to "CWS-R"
9.0 Ailerons Move in Direction of Right Roll
10.0 Auto Pilot Disengagement Indication on FDR
11.0 Airplane Brgins Roll to Right
12.0 Heading Select Engaged
13.0 Right Roll Continues to Overbank with Aileron Activity
14.0 F/O Autopilot announcements (CVR)
15.0 Raoid Left Roll Towards Wing Level
16.0 Impact with Water

Flash Airlines Sequence of Events - DRAFT
Seattle Edits Adapted from May 2004 Paris Meeting 10/1/04

### 2.5 Anaysis of the chronological main events

### 2.5.1 TO/GA Mode Disengages:

### 2.5.1.1 FDR Data:

FDR data shows TOGA on one side for only 1 or 2 seconds, other side unknown (all 13 flights with both A and B for different flights): for the accident flight, the TO/GA Mode was engaged at 92296 second, and was disengaged at 92297 second

Figure 2.5.1.1a TO/GA Mode Disengages (FDR data)

Figure 2.5.1.1b TO/GA Mode Disengages (FDR data)

TO/GA Observation within the last 25 Hours:

## SU-ZCF - FDR 25 Hour Data TOGA Observations

| Flight | Both <br> F/D ON? | Normal looking <br> A/T Takeoff | First <br> TOGA Push <br> $(1)$ | If Second <br> TOGA Push <br> $(1)$ |
| :---: | :---: | :---: | :---: | :---: |

| 13 | YES | YES | 2 |  |

(1) Number of samples recorded for TOGA_FCC (sample intvl=1 sec)

### 2.5.1.2 TO/GA Modes and Logic (Takeoff Mode Logic)

- Takeoff mode provides thrust control during the initial phase of the takeoff roll (0 to 80 knots).
- The takeoff mode is set by the takeoff/go-around switch, with the A/T armed for takeoff. The A/T is armed for takeoff when the airplane is on the ground, the Autothrottle is engaged, and the FMC takeoff mode is executed. If the A/T is engaged in go-around, the takeoff mode is inhibited. The takeoff mode is reset when the throttle hold logic is set, or the Autothrottle is disengaged.
(Refer to Boeing MM Chapter 22-31-00, Page 32)

Fig 2.5.1.2 Take Off Mode

### 2.5.1.3 TO/GA Mode Disengage Logic:

The TO/GA Mode disengages during the Take Off mode if the following logic is satisfied:
\{(Airspeed < 80 knots). [(One bad F/D switch input to one FCC) + (Bad squat switch input to one side) + (Landing gear up indication on one side) $\}+\{($ IRS instrument transfer switch in Both on X) + (Sensor signal invalid on one side) + (EFIS select switch in Both on X)\}
(Refer to Fig 2.5.1.3 TO/GA Mode Disengage Logic ${ }^{1}$ )

Fig 2.5.1.3 TO/GA Mode Disengage Logic

[^30]
### 2.5.1.4 TO/GA Mode Disengages analysis:

- FCC takeoff mode has not been operating properly for the entire 25 hours recorded on the FDR. Based on FDR data available, the cause for this either a bad squat switch (landing gear compressed) input to one FCC or a bad landing gear position indication to one FCC. In either case, the results is that pressing the TOGA button during takeoff would result in one FCC entering takeoff mode while the other enters go-around mode. This disagreement is detected and results in both FCCs dropping the TOGA mode2.

Fig 2.5.1.3.a TO/GA Mode Disengage Logic

[^31]- Since we see TOGA during both FCC A and FCC B TOGA events, one bad switch won't cause both. That makes the condition of "One bad F/D switch input to one FCC".
- The condition of $\{($ IRS instrument transfer switch in Both on X) + (Sensor signal invalid on one side) + (EFIS select switch in Both on X) \} leads to FD bars bias out of view, but does not reset mode. This is inconsistent with the FDR data which shows that the modes reset.
- Regarding the" Landing gear up indication on one side", the switch faults would result on one FCC entering Takeoff and one entering Go-Around mode. The FDR would record TOGA in either case, but the disagreement would cause both FCCs to reset TOGA mode.
- Regarding the "Bad squat switch input to one side", this fault would illuminate SPEED TRIM FAIL light on overhead panel during recall check. (ref 02:38:45 on CVR)

## Conclusion:

Based on the FDR data, the only possible causes for TOGA Mode Disengage are:

- Bad squat switch input to one side
- Landing gear up indication on one side.

There are no evidences that the TOGA mode disengagement has direct relation with the accident.
However, FDR data showed that this mode disengaged each time it was engaged. No crew report for this anomaly was found.

### 2.5.2 Aileron Movement during Takeoff

### 2.5.2.1 FDR data related to the event:

- Before T.O., with both ailerons at same deflection (neutral position), the FDR showed a bias of about one degree up ( 0.9696 degree)
- During the airplane roll on ground and up to about 80 kts speed, the left aileron deflected upwards towards trailing edge up (TEU) direction (to a maximum value of about 3.2 degrees which is equivalent to about 2.2 degrees after considering the neutral bias). The right aileron deflected downwards towards trailing edge down (TED) direction (to a maximum value of about -1.2 degrees which is equivalent to about -2.2 degrees after considering the neutral bias).
- At about 80 knots (frame 92305), the ailerons were deflected to neutral. The FDR showed new neutral bias at this speed of about 2.24 degrees.
- After 80 Knots, the FDR showed ailerons deflections towards right bank command up to time frame 92334 (about 6 seconds after airborn). The right aileron reached a maximum deflection of about 8.5 degrees (about 6.3 degrees from neutral). The left aileron reached a maximum deflection of about -5.6 degrees (about -7.8 degrees from neutral).
- The wind condition was 280/08 at Take Off. The aircraft was taking off from runway 22 R , with a relative wind direction of about 60 degrees. The cross wind component was about 6.9 kts blowing from the right side of the airplane.

Figure 2.5.2.1a Aileron Movement during Takeoff event

Figure 2.5.2.1b Aileron Movement during Takeoff event

Figure 2.5.2.1c Aileron Movement during Takeoff event

Figure 2.5.2.2 Wind direction during T.O

### 2.5.2.2 Aileron Float:

The left and right ailerons positions were related to the speed for the last 25 flying hours (for both PQ294 and PQ481 airplanes). Results are shown in the following figures ${ }^{1}$ :

## PQ294 FDR Aileron Position Aileron Float from Airload

Note: Positive Aileron is Trailing Edge Up
Figure 2.5.2.3a Aileron float from Airload (PQ294)

[^32]

Note: Positive Aileron is Trailing Edge Up

Figure 2.5.2.3b Aileron float from Airload (PQ481)

As shown from the above figures, the ailerons blow up as result of increasing speed is not exactly the same for all Take Off's. The aileron blow up increases with increasing speed.

Conclusion:

- Aileron movement direction during Takeoff is consistent with the wind condition existing during the Takeoff.
- Aileron bias change could be related to change in airplane speed.

Based on the FDR available date, there is no evidence that the aileron movement during Takeoff could gave direct relation with the accident.

### 2.5.3 FD Modes (Pitch \& Roll) Re-Engagement

Based on the CVR and FDR data:

- After takeoff and at 02:42:43 the captain called for HDG SEL "Four Hundred Heading select".
- At 02:42:44 First officer (F/O) confirmed "Four Hundred Heading select sir"
- At time 2:42:47, FDR data indicates Heading Select mode engaged (Radio Altitude indicated 371 feet AGL) (Frame 92341)
(Setting "HDG SEL" mode would restore the FD roll command bar).
- At 42:48 Captain called for Level Change
- At 02:42:49 First officer confirmed "Level Change, MCP speed, N1 Armed sir"
- At time 2:42:50, FDR data indicates Level Change mode engaged (Frame 92344)
(Setting "Level Change" mode would restore the FD pitch command bar).

Figure 2.5.3.1 FD Modes (Pitch \& Roll) Re-Engagement event

## Conclusion:

Setting "HDG SEL" and "Level Change" modes is normal and expected to restore the FD roll and pitch bars. These settings have no direct relations with the accident.

### 2.5.4 Roll Left and Left Turn Begun

The left turn is part of the planned departure pattern.
The crew received ATC clearance for a "left turn to intercept radial three zero six". This radial forms the airway to Cairo and involves a left turn of $274^{\circ}$ from runway 22. They briefed the departure and began the left turn as planned.

Note: Though not published, a $270^{\circ}$ turn is the customary night-time departure patterns from SSH and would have been familiar to the crew. The direction of turn (left or right) depends upon the runway used, but should be over the Red Sea. In fact, the FDR records that the accident crew successfully flew the mirror image pattern about 24 hours previously (right turn of $266^{\circ}$ from runway 4).

Figure 2.5.4.1 Roll Left and Left Turn Begun event

## Conclusion:

The Roll Left and the beginning of Left Turn are normal and expected to intercept and follow the Radial 306 to Cairo. These movements have no direct relation with the accident.

Figure 2.5.4.2 Roll Left and Left Turn Begun analysis

### 2.5.5 Roll back towards wing level

Based on the FDR data and at almost time frame 92419 second, the airplane left turn stopped and the wings became in level condition

Figure 2.5.5.1 Roll back towards wing level event
2.5.5.1 Conditions which could lead to this event
A. NA

B- Flaps assymetry:
The FDR did not show evidences of flap asymmetry. Based on these information, there is no evidence of flap asymmetry existing at the time of the event and consequently this condition could be ruled out

C- Slats assymetry:
C. 1 Uncommanded Deployment

Based on the performance evaluation, M-Cab results (Simulation match to FDR) this condition could be ruled out. (See section 2.5.13 Right roll continues to overbank with ailerons activities)

## C. 2 Remains Deployed (SLAT FULL DEPLOYED)

Based on the performance evaluation, M-Cab results (Simulation match to FDR) this condition could be ruled out. (See section 2.5.13 Right roll continues to overbank with ailerons activities)

D- Thrust assymetry
With reference to section "2.3.6. Power plants", it is shown that all the engines parameters were recorded in the FDR. However, some parameters data were not reliable (e.g. L engine N1). The other engines parameters are reliable including the N 2 for both engines.. Based on these information, there is no evidence of thrust assymetry existed at the time of the event and consequently this condition could be ruled out

## E- External Disturbance

This condition could be ruled out based on FDR data, M- Cab Simulator Match to FDR and meteorogical data

## F- Anomalies with the lateral control system

See Appendix 2-1 lateral control analysis, and section 2.5.13 Right roll continues to overbank with ailerons activities, Lateral control system

G- Pilot input.
This condition could not ruled out

### 2.5.5.2 M Cab results related to Simulated Failures (Spoilers, LE Slats)

Simulated failures:

1. Right outboard flight spoilers (\#7) Hardover simulation (hardover starts at 92391)
2. Left outboard flight spoilers (\#2) Hardover simulation (hardover starts at 92391)
3. Right outboard flight spoilers (\#7) Float simulation (floats starts at 92391)
4. Left outboard flight spoilers (\#2) Float simulation (floats starts at 92391)
5. Critical right wing leading edge slat \# 6 extends
6. Critical left wing leading edge slat \# 1 extends

It is to be noted that the results of the M-Cab tests as indicated in the appendix figures, show that the scenarios resulted from all the above mentioned simulated failures are not consistent with the accident scenario. Therefore, these simulated failures could be ruled out.
2.5.5.3 Roll Left and beginning of Left Turn possible causes:

After completing the process of elimination of the unlikely possibilities, the following conditions could be considered as possible causes leading to this event:

## 1- Widening Departure Pattern (intentional control action)

This possible cause is supported by the following evidences:

- $\quad$ Chief pilot reports some crews choose to widen their departure pattern by squaring turn at approximately $90^{\circ}$ to runway heading. The wings level heading, $140^{\circ}$, is $80^{\circ}$ from the runway heading.
- Although there was no specific briefing about widening pattern, the flight path is consistent with information provided by the Ex-Chief Pilot of Flash Airline concerning usual pattern
- The aircraft remained near heading 140 for 9 seconds. Roll rate decreases as aircraft nears 140.
- $\quad$ The PF (captain) may have wanted to ensure that he did not violate the local VOR altitude crossing practice.
- The previous day's departure from SSH included a 270 turn to right with altitude deviation

However, the following should be noted:

- The same crew made a similar departure about 24 hours previously, at a heavier weight without widening their departure and with altitude deviation.
- There is no discussion about this maneuver recorded on the CVR.
2- Mistaken understanding of "Initially 140 " (intentional)
- ATC clearance: "Destination Cairo as filed, climb initially flight level one four zero", F/O read back "destination Cairo via flight plan route one four zero". Captain later asked for confirmation about "Initially 140 " from F/O and for F/O to confirm with ATC. After initial clearance, neither ATC nor F/O specified whether "140" refers to a heading or altitude. Airplane rolls wings level on exactly 140.
- It has to be noticed that the crew never briefed the departure as it is usually done (headings, sets, displays,). Therefore all the dialogues between the Captain and the F/O before the turn is about " 140 ". From 2:41:19 to 2:41:40 it is clear that the Captain's mind is focused on a $140^{\circ}$ Heading: 2:41:19 F/O "left turn to establish 306", 2:41:29 Captain "initially 140". This match with what said Flash exChief pilot in his last statement about widening pattern. This might rule out "mistaken initial 140 heading interpretation".

However, the following evidences do not support this possibility assumption:

- No request from captain to set selected heading to 140.
- Did not ask for clarification of "Heading' clearance.
- "Initially" phrase refers to altitude, not heading.
- "14000" set in altitude window immediately after ATC clearance and was in the window during subsequent discussion and confirmation with ATC.
3- To level wings prior to engaging autopilot (intentionally)
On FDR previous flight, the same crew did not engage the AP until wings level at approximately 9000 ft following completion of a series of turns after takeoff
However, On FDR flight, the crew engaged the autopilot in the middle of a $270^{\circ}$ turn at a bank angle of 20 to $25^{\circ}$.

4- Pilot loses awareness of heading or bank (unintentional)
Roll out coincident with passing over coastline and resulting loss of outside visual references. Pitch begins to deviated from expected value. Misleading vestibular cues were present. However, attitude information available on displays to 3 flight deck occupants.

## Conclusion:

The investigation could not determine a higher possibility to any of the above findings based on the given data.

Updated: 10/1/04 (Seattle)

### 2.5.6 Pitch up and airspeed decay

Based on the FDR data the speed reached 217 Kt at time frame 92405 (seconds), but the speed decreased to 184.5 Kts at 92437.

Figure 2.5.6.1 Pitch up and airspeed decay

Pitch up and airspeed decay analysis:
The possible conditions which might lead to this event are shown in the following:

1. Pilot Wanted to Gain Altitude Quicker (Intended Maneuver)

This possibility may be supported by the fact that the airplane should intercept the VOR radial at a minimum of $11,000 \mathrm{ft}$
2. Pilot Following Erroneous FD (intended)

There are not enough data to rule in or rule out this probability
3. Relaxation of Control in Out of Trim Condition (Unintended Maneuver) The results from the M-CAB tests match with FDR
4. Autopilot Fault (Unintended Maneuver)

This condition might be ruled out. This event started prior to AP Engagement (based on FDR data)
5. Stab Trim Fault (Unintended Maneuver)

This condition might be ruled out. Based on FDR data, the stabilizer did not show abnormal behavior throughout the flight.
6. Pilot pulling on the control column (unintentional)

## Conclusion:

With the exclusion of the ruled out (conditions 4 and 5), the investigation could not determine a higher possibility to any of the remaining conditions (conditions 1, 2, 3 and 6) based on the given data.

In all cases, this event does not have direct relation to the accident

### 2.5.7 Autopilot engage sequence

Based on the CVR data, the Captain announced 'Autopilot" at 92409, followed by "Not yet" at 92412. At 92413 FDR showed A/P engaged+ CWS-R

Figure 2.5.7.1 Autopilot engage sequence

## Autopilot Engage Logic

| Failure to Sync or Pressurize Scenarios |  |
| :---: | :---: |
| 1-Failure to synchronize | 4.0 sec |
| 2-sync in $0+$ sec but fails to pressurize | 3.5 sec |
| 3 -sync in 4-sec but fails to pressurize | 7.5 sec |

Figure 2.5.7.2a Autopilot Engage Logic

[^33]
## A/P Engage Function

Figure 2.5.7.2b Autopilot Engage Logic

If the pre-engage logic is valid, pushing any of the autopilot switches (push/light type switches CMD and CWS) engages the autopilot and turns the light on. Once the light is on, a loss of the engage hold logic causes the light to go off and the autopilot disengages. If the pre-engage logic is not valid when the switch is pressed, the light does not turn on and the autopilot does not engage.

Table 2.5.7.2 Autopilot Engage, Engage Hold Logic
2.5.7.2 Autopilot engagement attempt analysis based on the FDR and CVR data:
2.5.7.2.1 Based on the FDR recorded data, the autopilot was engaged for few seconds and then disengaged, meaning that the pre-engage logic was valid, i.e. the following logic was valid:

- Pitch CWS force was not greater than 5 lbs, and
- Roll CWS force was not greater than 2.25 lbs , and
- Elevator Detent Pressure Switch indicates no pressure, and
- Aileron Detent Pressure Switch indicates no pressurized, and
- Auto Stab Trim Cutout Switch was not in Cutout, and
- Both Flap Switches and Stab Trim Motor agree as Flaps Up or as Flaps Down, and
- Main Electric Trim Switch not Activated, and
- Aileron Force Limiter position agrees with Flaps UP or Flaps Down, and
- CAS valid, and
- Uncorrected Altitude valid, and
- 26 VAC 400 Hz valid, and
- MCP to FCC Bus valid, and
- Pitch Angle valid, and
- Pitch Rate valid, and
- Roll Angle valid, and
- Roll Rate valid, and
- Baro Altitude
2.5.7.2.2 The conditions leading to the event of engaging the autopilot are presented in the following:

1. Captain requests autopilot, Captain cancels request, F/O pushes CMD button anyway

This probability is consistent with Flash Airline company practice. Impression from CVR is that the first officer is manipulating the MCP Controls prior to autopilot engagement.CMD button is located on right side of MCP, closer to F/O.

However, Boeing procedure is for "pilot flying" to push the CMD button.
2. Captain requests autopilot, Captain prompts F/O due slow response, F/O pushes CMD button

This probability is consistent with Flash Airline company practice Impression from CVR is that the first officer is manipulating the MCP, Controls prior to autopilot engagement, CMD button is located on right side of MCP, closer to F/O.

However, Boeing procedure is for "pilot flying" to push the CMD button.
3. Captain pushes CMD button, gets no response., Captain questions no response and makes second push., F/O reports autopilot engaged.

Boeing procedure is for "pilot flying" to push the CMD button

## Conclusion:

The investigation could not determine a higher possibility to any of the above findings based on the given data. However, with reference to the CVR/ FDR correlation, this event could have initiated crew distraction.

Figure 2.5.7.3 Autopilot Engage Attempt with Time Aligned Data

The CVR statement "Not yet" at 412 is attributed to Captain instead of the Observer

Figure 2.5.7.4 Autopilot Engage Attempt with Time CVR Data

Figure 2.5.7.5 Autopilot Engage fault Tree Analysis

### 2.5.8 Mode change from HDG SEL to CWS-R

At 92413 FDR showed A/P engaged+ CWS-R

Figure 2.5.8 Mode change from HDG SEL to CWS-R
2.5.8.1 Possible conditions leading to "Heading Select Mode Fails Off"

1. Loss of TAS (True Air Speed)

Unlikely to be the cause of the event as it would have also caused loss of level change. Level change was not lost
2. Loss of "Magnetic Heading" Unlikely to be the cause of the event because the Magnetic Heading was available immediately before and is valid on FDR
3. MCP (Mode Control Panel) Fault This condition could be ruled out
3. FCC Fault (Unpredictable)

This condition could be ruled out
5. CWS Manually Selected (no failures condition)

Unlikely to occur simultaneously with AP engagement
6. 10 lbs (or higher) of wheel force ((no failures condition)

Unlikely to occur without recorded aileron motion
7. AP Engagement with FD Roll Bar > 7 Degrees (with time lag) (no failures condition)
If the FD director command is greater than 7 degrees at the time autopilot engagement is attempted, the roll mode will change from HDG SEL to CWS. According to FDR data this seems to be consistent with the probable FD command which existed when A/P engagement was initiated.
This condition could not be ruled out.

## Conclusion:

After ruling out the conditions which are unlikely to occur as mentioned above, the possible condition that could have led to this event is that the autopilot was Engaged with FD Roll Bar > 7 Degrees (with time lag)

Updated: 10/1/04 (Seattle)

### 2.5.9 Aileron move in direction of right roll

Based on the FDR, the ailerons started moving in the direction requesting for airplane right roll almost after 92392

Figure 2.5.9.1a Aileron Move in direction of right roll

Figure 2.5.9.1b Aileron Move in direction of right roll

Based on the FDR data, and starting from about the time frame 92393 the right aileron showed upward movement (TEU), the left aileron showed downward movement. This movement dirction continued up to the 92471 timeframe after which airplane recovery attempt was made.

Probable conditions leading to the event:
A. NA:

B- Flaps assymetry:
The FDR did not show evidences of flap asymmetry. Based on these information, there is no evidence of flap asymmetry existing at the time of the event and consequently this condition could be ruled out

C- Slats assymetry:

### 1.1 Uncommanded Deployment

Based on the performance evaluation, Slat failure simulations that were conducted on computer workstations, this condition could be ruled out. (See section 2.5.13 Right roll continues to overbank with ailerons activities)

### 1.2 Remains Deployed (SLAT FULL DEPLOYED)

Based on the performance evaluation, M-Cab results (Simulation match to FDR) this condition could be ruled out. (See section 2.5.13 Right roll continues to overbank with ailerons activities)

D- Thrust assymetry
With reference to section "2.3.6. Power plants", it is shown that all the engines parameters were recorded in the FDR. However, some parameters data were not reliable (e.g. L engine N1). The other engines parameters are reliable including the N 2 for both engines.. Based on these information, there is no evidence of thrust assymetry existing at the time of the event and consequently this condition could be ruled out

E- External Disturbance
This condition could be ruled out based on FDR data, M- Cab Simulator Match to FDR and meteorogical data

F- Lateral control system

1- Pilot input
This condition could not be ruled out
2- Autopilot Initiated

- CWS Bank Hold

In this condition, the autopilot would command faired ailerons. Thus, this condition could be ruled out

- CWS Heading Hold

Normally this mode would not engage past 6 deg of airplane bank. The roll angle as shown by the FDR was higher than 6 degrees. Thus, this condition could be ruled out

3- Lateral system fault:
See Appendix 2-1 lateral control analysis, and section 2.5.13 Right roll continues to overbank with ailerons activities, item 1.1 Lateral control system

## Conclusion:

The investigation could not determine a higher possibility to any of the above findings (lateral system fault, pilot input) based on the given data.

Updated: 10/1/04 (Seattle)

Updated: 10/1/04 (Seattle)

### 2.5.10 Autopilot Disengagement indications on the FDR and CVR

Based on FDR and CVR information:

- At time 02:43:55 (92409), the Captain called "Autopilot".
- At time 02:43:58 (92412), the Captain stated "Not yet".
- At time 02:43:59 (92413), the FDR recorded the autopilot was engaged, and the roll mode transition to CWS-R ${ }^{1}$.
- At time 02:44:00 (92414), the F/O stated "Autopilot in command sir".
- At time 02:44:01 (92415), the captain stated "EDEELO", (an Arabic exclamation expressing a sharp response of some kind). At the same time, the FDR records momentary aileron surfaces movements. The right aileron deflected to 7.2 degree TEU for one second
- At time 02:44:02 (92416), the CVR recorded the autopilot disconnect warning and the FDR recorded the autopilot disengaged. The aural warning lasted for 2.136 seconds. During this time, an increase in pitch and decay in airspeed were observed

[^34]

AIRPLAMES WITH HECHANICAL AILERON FORCE LIMITER

Table 2.5.10.1 Autopilot Unlock, Hold, Disengage Logic

## Autopilot Engage \& Engage Hold Interlocks

|  |  | Pre- <br> Engage |  | Engage <br> Hold |
| :--- | :---: | :---: | :---: | :---: |
|  | Condition | Prevent |  |  |
| Engage |  |  |  |  | | Cause |
| :---: |
| Disengage |

Table 2.5.10.2 Autopilot Engage, Engage Hold interlock

Autopilot "Engaged" means:
Autopilot system began an attempt to synchronize so that it could subsequently control the airplane. It does not necessarily mean that the detent pistons were pressurized and that
the autopilot was controlling the airplane.
This definition is consistent with indications of autopilot engagement available to crew and FDR.

Autopilot disengagement:
Any of the following three conditions cause autopilot disengagement:
A. The engage synchronization (actuator to surface) \& pressurization failed to complete
(Failure to synchronize $4.0 \mathrm{sec} / \mathrm{sync}$ in $0+\mathrm{sec}$ but fails to pressurize $3.5 \mathrm{sec} /$ sync in $4-\mathrm{sec}$ but fails to pressurize 7.5 sec )

## Autopilot Engage Logic

| Failure to Sync or Pressurize |  |
| :--- | ---: |
|  | Scenarios |
| 1-Failure to synchronize light ON |  |
| 2-sync in $0+$ sec but fails to pressurize | 4.0 sec |
| 3-sync in 4-sec but fails to pressurize | 7.5 sec |

Figure 2.5.10.2 Autopilot Engage Logic
A. 1 The engage synchronization:

The first step of autopilot engagement is synchronization. The arm solenoid opens and the FCC issues transfer valve commands to move the autopilot pistons to match the current location of the output crank. However, since the detent solenoid is closed, the detent pistons are free to move and the autopilot piston motion does not affect the output crank to the lateral system.
The FDR receives the ailerons position data; however, the autopilot actuator piston position is not recorded.

ROLL CHANNEL A/P ACTUATORS AND POSITION SENSOR

Fig 2.5.10.3 Roll channel autopilot actuator and position sensor ${ }^{2}$

[^35]

Fig 2.5.10.3 Spoiler sensor

Fig 2.5.10.3 Autopilot Actuator

## A. 2 Pressurization:

Hydraulic pressure must be sensed at the autopilot aileron hydraulic switch (pressure switch on the autopilot actuator) within 3.5 seconds after actuator detent solenoid engaged; however, the FDR does not record data regarding the hydraulic pressure at the autopilot aileron hydraulic switch.
B. The engage hold interlocks not satisfied

Any of the following conditions cause autopilot disengagement:

- $\quad$ Auto Stab Trim Cutout Switch in Cutout (status is not recorded in the FDR).
- Both Flap Switches and Stab Trim Motor don't agree as Flaps Up or as Flaps Down (switches status are not recorded in the FDR).
- Main Electric Trim Switch Activated (status is not recorded in the FDR).
- Aileron Force Limiter position does not agree with Flaps UP or Flaps Down
- $\quad$ CAS Invalid (status is not recorded in the FDR).
- Uncorrected Altitude Invalid (status is not recorded in the FDR).
- $\quad 26$ VAC 400 Hz Invalid (status is not recorded in the FDR).
- MCP to FCC Bus Invalid (status is not recorded in the FDR).
- $\quad$ Pitch Angle Invalid (status is not recorded in the FDR).
- $\quad$ Pitch Rate Invalid (status is not recorded in the FDR).
- Roll Angle Invalid (status is not recorded in the FDR).
- Roll Rate Invalid (status is not recorded in the FDR).
- Baro Altitude Invalid (status is not recorded in the FDR).
- Elevator Detent Pressure Switch Indicates non-pressurized (status is not recorded in the FDR).
- Aileron Detent Pressure Switch Indicates non-pressurized (status is not recorded in the FDR).
C. Autopilot manually disconnected.

It is to be noted that the autopilot disconnect switches status on the control wheels horns are not recorded in the FDR.
2.5.10.2 Autopilot Disconnect Analysis (based on FDR and CVR available data):

The CVR statement "Not yet" is not attributed to the observer but to the Captain.
2.5.10.3 Probable conditions for autopilot disconnect:

1. Case of "Autopilot Engages but Disengages Approximately 3.6 seconds after Flight Crew Selects On"

### 1.1 Manual Disconnect

Warning length is consistent with "double click" typical of manual disconnects (within allowable warning duration tolerance). However, there is no disengagement callout by crew on CVR. In addition, the autopilot disconnect switches status on the control wheels horns are not recorded in the FDR.
Note:

- Boeing presentation (see 2.5.10.2) regarding autopilot function states that the duration of autopilot manual disconnect warning is less than 2 seconds
- Honeywell verbal information, states the duration of autopilot manual disconnect warning is max of 3 seconds
- $\quad$ Actual time of warning based on CVR is 2.136 seconds

Although requested, Honeywell did not supply the investigation team with any supporting evidence.

### 1.2 Automatic Disconnect

A. Interlock invalid

All interlocks were valid 3 sec earlier during autopilot engagement.
This scenario requires one of the interlocks to become invalid during the 3 seconds and autopilot was engaged.
B. Synchronization did not complete
(FDR shows disconnect prior to min 3.695 seconds this scenario requires)
B. 1 Actuator never matches surface position
B. 2 Detent pressure sensed prior to detent command This condition presumes:

- Detent solenoid stuck open prior to engagement attempt
- Transfer valve jammed off center (Does not match FDR data as autopilot would disconnect within 182 ms )

## 2. Case of Autopilot Does Not Engage ${ }^{3}$

This case can be ruled out because the FDR shows that the autopilot did engage and the disconnect warning can be heard on the CVR.

## Conclusion:

The investigation could not determine a higher possibility to any of the above findings (Autopilot automatically disengaged or manually disengaged), based on the given data.

[^36]
"Engaged" means
AP system began an attempt to synchronize
so that it could subsequently control the
airplane. It does not necessarily mean that
the detent pistons were pressurized and that the AP was controlling the airplane.
This definition is consistent with indications of
AP engagement available to crew and FDR.

FDR shows disconnect prior to min 3.695 seconds this scenario requires

This condition presumes:
Detent solenoid stuck open prior to
engagement attempt
Transfer valve jammed off center
Does not match FDR data as
during AP engagement
This scenario requires one of the
interlocks to become invalid during
the 3 seconds and AP was engaged.

AP would disconnect within 182 ms

This definition is consistent with indications of AP engagement available to crew and FDR.

## Legend:

Sufficient Data Collected at This Point

May Need More DataNot Eval'd for Data Needs

FDR shows disconnect prior to min 3.695 seconds this scenario requires

This condition presumes:
Detent solenoid stuck open prior to engagement attempt
Transfer valve jammed off center
Does not match FDR data as
AP would disconnect within 182 ms
Updated: 10/1/04 (Seattle)
Cairo 3 Feb 05

### 2.5.11 Airplane begins roll to right

Based on the FDR data, the airplane stopped the left turn and started a right turn at about 92420

Figure 2.5.11.1 Airplane begins roll to right

### 2.5.11.1 Conditions which could lead to this event

A. NA

## B- Flaps asymmetry:

The FDR did not show evidences of flap asymmetry. Based on these information, there is no evidence of flap asymmetry existing at the time of the event and consequently this condition could be ruled out

C- Slats asymmetry:
C. 1 Uncommanded Deployment

Based on the performance evaluation, M-Cab results (Simulation match to FDR) this condition could be ruled out. (See section 2.5.13 Right roll continues to overbank with ailerons activities)
C. 2 Remains Deployed (SLAT FULL DEPLOYED)

Based on the performance evaluation, M-Cab results (Simulation match to FDR) this condition could be ruled out. (See section 2.5.13 Right roll continues to overbank with ailerons activities)

D- Thrust asymmetry:
With reference to section "2.3.6. Power plants", it is shown that all the engines parameters were recorded in the FDR. However, some parameters data were not reliable (e.g. L engine N1). The other engines parameters are reliable including the N 2 for both engines.. Based on these information, there is no evidence of thrust assymetry existed at the time of the event and consequently this condition could be ruled out

## E- External Disturbance

This possibility could be ruled out based on FDR data, M- Cab
Simulator Match to FDR and meteorogical data

## F- Flight Crew Believes Autopilot is Engaged When it is not <br> Reference to FDR, CVR data and Crew Behavior studies, this condition could not be ruled out <br> CVR clearly records F/O announcement "Autopilot in command" on later "No autopilot commander". This strongly supports the above statement " F "

G- Lateral control system:
1- Pilot Input

### 1.1 Following FD

1.1.1 FD Commands Erroneous ${ }^{1}$
1.1.1.1Erroneous Heading

FDR records heading data used by FD - not erroneous. This condition could be ruled out
1.1.1.2 Erroneous Roll Data

FDR records roll data used by FD - not erroneous. This condition could be ruled out
1.1.1.3 Erroneous Selected Heading Data

Selected heading recorded on FDR, but only once every 64 seconds.
1.1.1.4 FD Computational Fault Based on systems evaluation, this condition could be ruled out
1.1.1.5 Erroneous roll rate data

FDR records roll data used by FD - not erroneous
Correct roll data requires correct roll rate data. This condition could be ruled out
1.1.2 FD Commands Correct Unintended Direction of Selected Heading (to right of current heading)
1.1.2.1 Erroneous heading data to F/O EADI and F/O selects heading based on relative displacement to erroneous heading. This condition could be ruled out

[^37]
### 1.1.2.2 Manual Input to MCP

This condition could be ruled out
1.1.2.3 Erroneous heading data to Captain EADI CAPT heading data on FDR is accurate. This condition could be ruled out
1.2 Widening His Departure Pattern

N/A to this portion of flight. This condition could be ruled out
1.3 Mistaken Initial 140 Heading Interpretation

N/A to this portion of flight. This condition could be ruled out
1.4 To Level Wings Prior to Autopilot Engagement N/A to this portion of flight. This condition could be ruled out
1.5 Following Erroneous EADI

FDR attitude data (same as left EADI data) is normal.
EADI does not have failure modes which result in display of erroneous attitude data (with correct IRU input). This condition could be ruled out
1.6 Reaction to Uncommanded Roll

From the performance point of view; the FDR match w.r.t external disturbance. External disturbance is inconsistent with FDR/ Performance data. This condition could be ruled out
1.7 Pilot Loses Situational Awareness See Section 2.6.1 Crew Behavior Subcommittee, this condition could not be ruled out

2- Autopilot Initiated
2.1 Commanded

Based on FDR, this condition could be ruled out
2.2 Uncommanded (actuator faults only)
(See section 2.5.13 Right roll continues to overbank with ailerons activities, item 6.2.2.3.1 Actuator Hardover without Force Limiter 17 to 20 lb Force) This condition could not be ruled out.

3- Lateral System Fault
3.1 Jam
3.1.1 Between Wheel and PCU
(FDR showed ailerons movements in both directions (both ailerons)

Performance; FDR Match)
These conditions could be ruled out

3.1.2 Between PCU and Aileron<br>(FDR showed ailerons movements in both directions (both ailerons)<br>Performance; FDR Match)<br>These conditions could be ruled out

### 3.2 PCU Fault

This condition could be ruled out (Systems Evaluation)
See Appendix 2-1 lateral control analysis.
This condition could be ruled out

### 3.3 Cable Break

3.3.1 Between Wheel and PCU
(FDR showed ailerons movements in both directions (both ailerons)
Performance; FDR Match)
These conditions could be ruled out

### 3.3.2 Between PCU and Aileron <br> (FDR showed ailerons movements in both directions (both ailerons) <br> Performance; FDR Match) <br> These conditions could be ruled out

3.4 Trim/Feel Unit Fault

This condition could not be ruled out
(See Section 2.5.13 Right roll continues to overbank with ailerons activities, item 6.3.4 Trim/Feel Unit Fault.)
3.5 Spoiler Fault

### 3.5.1 Spoiler Hardover

These conditions could be ruled out based on M-Cab results
See Section 2.5.13 Right roll continues to overbank with ailerons activities, item 6.3.5 Spoiler Fault

### 3.5.2 Spoiler Float <br> These conditions could be ruled out based on M-Cab results See Section 2.5.13 Right roll continues to overbank with ailerons activities, item 6.3.5 Spoiler Fault

## Conclusion

After completing the process of elimination of the unlikely conditions shown above, the investigation could not determine a higher possibility to any of the above findings based on the given data.

Updated: 10/1/04 (Seattle)

FDR attitude data (same as left EADI data) is normal.
EADI does not have failure modes which result in display of erroneous attitude data (with correct IRU input)
Check on displaced airplane reference symbol mode shown in AMM

See lateral system fault
pilot input study

Updated: 10/1/04 (Seattle)

See Honeywell Presentation. 3 Feb 05 No FCC faults or combination of faults result in valid FDR data wtih erroneous commands.

Updated: 10/1/04 (Seattle)

Updated: 10/1/04 (Seattle)

### 2.5.12 Heading Select engaged

- At time 02:44:05 (92419), the Captain requested "heading select".
- At time 02:44:07 (92421), the F/O states "heading select" and the FDR records heading select mode engaging.

Figure 2.5.12.1 Heading Select engaged

Figure 2.5.12.2 Heading Select (FDR, CVR)

Heading Select engaged might be engaged as a result of the following:

- Manual selection
(Supported by CVR informatio)

### 2.5.13 Right roll continues to overbank with ailerons activities

Based on the FDR and the CVR data, the airplane continued the right overbank until a maximum of 111 degree at about 92472 .

Figure 2.5.13.1a Right roll continues to overbank with ailerons activities

The conditions which may lead to the event are presented in the following:

1. Slat Asymmetry
1.1 Uncommanded Deployment

Based on the performance evaluation, M-Cab results (Simulation match to FDR) this condition could be ruled out. (See following M-Cab results figures)
1.2 Remains Deployed (SLAT FULL DEPLOYED)

Based on the performance evaluation, M-Cab results (Simulation match to FDR) this condition could be ruled out. (See following M-Cab results figures)

Figure 2.5.13.2a Critical right L.E. Failure- Slat \#6 extends (longitudinal)

Figure 2.5.13.2b Critical right L.E. Failure- Slat \#6 extends (lateral)

Figure 2.5.13.3a Critical left L.E. Failure- Slat \#1 extends (longitudinal)

Figure 2.5.13.3b Critical left L.E. Failure- Slat \#1 extends (lateral)
2. Thrust Asymmetry

With reference to section "2.3.6. Power plants", it is shown that all the engines parameters were recorded in the FDR. However, some parameters data were not reliable (e.g. L engine N1). The other engines parameters are reliable including the N2 for both engines.. Based on these information, there is no evidence of thrust assymetry existing at the time of the event and consequently this condition could be ruled out
3. NA
4. External Disturbance

This condition could be ruled out based on FDR data, M- Cab Simulator Match to FDR and meteorogical data
5. Flap Asymmetry

The FDR did not show evidences of flap asymmetry. Based on these information, there is no evidence of flap asymmetry existing at the time of the event and consequently this condition could be ruled out
6.1 Flight Crew Behavior
6.1.1 Pilot Input

### 6.1.1.1 Following FD

### 6.1.1.1.1 FD Commands Erroneous

> 6.1.1.1.1.1 Erroneous Heading Data
> This condition will not command past bank angle limit, thus this condition could be ruled out
6.1.1.1.1.2 Erroneous Roll Data
(L IRU roll data on FDR is correct), ,
thus this condition could be ruled out
6.1.1.1.1.3 FD Computational Fault; FCC computer fault Based of the analysis of the A/P faults, this condition could be ruled out
6.1.1.1.1.4 Erroneous Roll Rate Data

L IRU roll data on FDR is correct; therefore roll rate data must be accurate.
(Supported by M-Cab test results), thus this condition could be ruled out
6.1.1.1.1.5 Erroneous Selected Heading Data
This condition will not command
past bank angle limit. Supported by
system evaluation; (Supported by M-
Cab test results), thus this condition
could be ruled out

### 6.1.1.1.2 FD Commands Correct

### 6.1.1.1.2.1 Unintended Direction of Selected HDG (to right of current HDG)

6.1.1.1.2.1.1 Manual Input to MCP FD would not command overbank if correct. (Supported by System Evaluation; M-Cab test results), thus this condition could be ruled out

### 6.1.1.2.1 Captain EADI Erroneous

6.1.1.2.1.1 Erroneous Attitude Data from IRU L IRU data is correct on FDR, (Supported by system evaluation; FDR data common), thus this condition could be ruled out

### 6.1.1.2.1.2 Symbol Generator Fault

### 6.1.1.2.1.2.1 Blanking; SG Fail

 Based on System Evaluation, no indication would occur, thus this condition could be ruled out6.1.1.2.1.2.2 Offset Airplane Reference

Based on systems
evaluation, this condition
could be ruled out

### 6.1.1.2.2 Alternate Instruments Not Cross-Checked

No information was available to exclude this condition, therefore this condition could not be ruled out
6.1.1.3 Reaction to Uncommanded Roll (pilot interaction with fault) From the performance point of view; the FDR match with respect to external disturbance. External disturbance is inconsistent with FDR/ Performance data, this condition could be ruled out

### 6.1.1.4 Pilot Loses Situational Awareness

### 6.1.1.4.1 Captain experiences SD Type II

Based on the outcome of the Crew Behavior Subcommittee studies, this condition could not be ruled out
6.1.1.4.2 Captain misinterprets ADI indications

See Section 2.6 Crew Behavior

### 6.2.1 Commanded

6.2.1.1 CWS-R

Autopilot does not command past bank angle limit. Therefore this condition will not cause overbank. (Supported by M-Cab evaluation), thus this condition could be ruled out
6.2.1.2 All Other Modes

Autopilot does not command past bank angle limit. Therefore does not cause overbank. (Supported by Systems Evaluation; FDR Data), thus this condition could be ruled out
(It is to be noted that the $\mathrm{A} / \mathrm{P}$ does not command past bank angle limit. Therefore this condition will not cause overbank).

### 6.2.2 Autopilot Malfunction

### 6.2.2.1 FCC Fault

### 6.2.2.1.1 Failure of Bank Angle Limit Function

 No FCC internal faults can lead to autopilot engagement or erroneous commands FCC Fault Monitoring Disconnected, thus this condition could be ruled out ${ }^{1}$
### 6.2.2.1.2 Other FCC Internal Faults

No FCC internal faults can lead to autopilot engagement or erroneous commands FCC Fault Monitoring Disconnected, thus this condition could be ruled out (see footnote \#1)

### 6.2.2.2 MCP Fault (SCENARIO 9 10A, 10B, 10C Erroneous Selected Heading)

This scenario requires:
Autopilot failure to engaged state but outputting disengaged status data to FDR
FDR Bank data-fault does not affect bank angle limits Thus this condition could be ruled out

### 6.2.2.3 Autopilot Actuator Fault

[^38]6.2.2.3.1 Actuator Hardover without Force Limiter 17 to 20 lb Force
6.2.2.3.1.1 Both Solenoids and Transfer Valve Jammed (Autopilot actuator, both Solenoids and Transfer Valve Jammed (Actuator Hardover without Force Limiter 17 to 20 lb Force))
(Refer to appendix 2-1 lateral control analysis, Table 3 Hypothetical failures scenarios [Autopilot Actuator], Scenario 4)

Assumptions:

- $\quad$ These faults require 3 concurrent faults. Detent solenoid was in correct position at autopilot engagement. Arm solenoid could be latent failure. Transfer was working on previous flight and could have occurred anytime after last use of autopilot and would have been latent from that point.
- Both the Arm and the Detent solenoid are assumed to fail (stuck open). The transfer valve is assumed to fail in the position commanding right bank

The cause of these failures can not be conclusively identified. However the failure of the arm solenoid (stuck open solenoid) might have been the result of a stuck closed contact (MCP engage relay A). Also these failures might be the result of an electric short within the electrical socket on the autopilot actuator.

Consequences of the hypothetical failures:

- $\quad$ This triple fault will result in an A/P actuator hardover.
- The autopilot can not be engaged.
- Detent pressure switch will sense hydraulic pressure before engagement; therefore, the preengagement logic will not be valid preventing engagement of autopilot.
- With autopilot disengaged, both aileron wheels will be driven away of the neutral position and will be positioned at about 60 degrees wheel position (Refer to figure 2.5.13.5, forces versus wheels position)
- $\quad$ The ailerons and flight spoilers will follow movement of the ailerons control wheels.
- The affected autopilot actuator will always try to drive the ailerons and spoilers towards the actuator hardover position
- The authority of the autopilot is shown in Figure ".5.13.5 "Ailerons and spoilers behavior with autopilot actuator hardover"
- The Captain will be able to control the ailerons and flight spoilers with an additional force of 17 lbs to overcome detent piston pressure and override the autopilot actuator.
- Whenever the control wheels are released, the control wheel will tend to return to the relevant autopilot actuator hardover position (60 degrees wheel position), resulting in an aileron deflection of about $\pm 13$ degrees and spoilers deflection.
- This fault will not be associated with any visual or audio warning in the cockpit

This condition could not be ruled out, based on the following:

- $\quad$ The results obtained from the analytical studies and the M-Cab test show a very close consistency with the available data.
- With reference to FDR data and after autopilot disconnect, the FDR shows tendency for the ailerons to move towards right turn direction. Movement of the aileron surfaces as shown in the FDR towards the neutral
position could be explained by crew attempts to control the airplane attitude with the existence of the failure. The rate of airplane rolling to the right is always reduced with these attempts. The forces required to move the ailerons by the captain are higher than the forces required in normal condition with no fault.
- Whenever the control wheels are released, the ailerons move towards the offset position showing high consistency with the fault existence. The fault was continually driving the airplane towards more right roll The movements of the ailerons throughout the last recovery phase highly support this scenario. The FDR data shows that even with the captain attempt to recover the airplane at the last stages, the ailerons always had the trend to move towards the opposite direction of correction which is highly consistent with the fault existence when the captain effort to restore the airplane is reduced.

Therefore, it could be concluded that this hypothetical condition shows close consistency with the event. This condition is also consistent with the possibility of recovering the airplane when appropriate quantity of input is applied timely on the airplane ( $\mathrm{M}-\mathrm{Cab}$ tests).
(See also section 2.6 Crew
Behavior)
This condition could not be ruled out
Scenario 12d - Both Solenoids Stuck Open with Transfer Valve Jammed
This triple fault will result in an A/P actuator hardover. The force limit of the actuator still operates normally.
Hyd System Pressure
Mod Piston Command
Pressure
Detent Piston Reduced
Pressure
Return Pressure

Figure 2.5.13.4 Autopilot Actuator

## 737-300 Lateral Control System - Autopilot Operation

Figure 2.5.13.5 Ailerons and spoilers behavior with autopilot actuator hardover
6.2.2.3.1.2 Both Solenoids, Transfer Valve, and Pressure Regulator Jammed Inconsistent, based on M-Cab results and systems evaluation, thus this condition could be ruled out
6.2.2.3.1.3 Both Solenoids, Transfer Valve, and Relief Valve Jammed

Inconsistent, based on M-Cab results and systems evaluation, thus this condition could be ruled out
6.2.2.3.2 Actuator Hardover with 80 lb Force
6.2.2.3.2.1 Both Solenoids, Transfer Valve, Pressure Regulator, and Relief Valve

Fighting 80 lbs of wheel force is a significant effort which prohibits normal breathing/ speech patterns (inconsistent with CVR data), thus this condition could be ruled out
6.2.2.3.2.2 Shearout Does Not Break

Fighting 80 lbs of wheel force is a significant effort which prohibits normal breathing/ speech patterns (inconsistent with CVR data), thus this condition could be ruled out
6.2.2.3.3 No Autopilot Input to Lateral Control System (Latent Fault)
6.2.2.3.3.1 Arm Solenoid Stuck Open

Based on system evaluation, this fault is latent and does not cause any anomalous system operation. (having no lateral system input).
(Sys Evaluation; this fault has no lateral system input)

Based on system evaluation, this fault is latent and does not cause any anomalous system operation. (having no lateral system input).

6.2.2.3.4 Additional 17 lb Centering Force on CW, Arm and Detent Solenoid Stuck Open (SCENARIO 12C)<br>This fault causes an increase in centering force, but does not create any tendency for right roll, thus this condition could be ruled out

### 6.2.2.4 Sensor Faults

### 6.2.2.4.1 Spoiler Sensor Fault

This scenario requires:
Autopilot failed to "engaged" state but outputting disengaged status data to FDR (System Evaluation).

Spoiler sensor data is not used with flaps up.
Autopilot not engaged.
Autopilot would not command overbank and would still follow correct path command (if it was engaged). (Supported by system evaluation)

Thus this condition could be ruled out

### 6.2.2.5 IRU Faults

All the following scenarios require:

1. Autopilot failed to "engaged state" but outputting disengaged status data to FDR 2. FCC must command airplane to bank angle above 30 degrees

No FCC internal faults can lead to A/P engagement or erroneous commands)
6.2.2.5.1 IRU Shutdown

Not supported by FDR Data, thus this condition could be ruled out
6.2.2.5.2 Erroneous L IRU Output of Roll Rate
FDR records roll data used by FD - not erroneous Correct roll data requires correct roll rate data (Supported by System Evaluation + FDR data), thus this condition could be ruled out
6.2.2.5.3 R IRU of NCD for Roll Rate (This scenario requires1 Autopilot failed to "engaged" state but outputting disengaged status data to FDR.
2 Internal faults within IRU that allow incorrect roll data to be transmitted to FCC, EADI (Supported by System evaluation + FDR)
Thus this condition could be ruled out
6.2.2.5.4 Erroneous R IRU Output of Straight and level flight during bank
Would result in:

1. Autopilot actuator hardover.
2. Captain FD would provide correct steering cues
3. F/OEADI would display straight and level flight ("Overbank annunciations must therefore be based on some other source")
4. F/OFD would display erroneous steering cues
5. Roll comparator annunciated

Thus this condition could be ruled out
6.3 Lateral System Fault
(See Appendix 2-1 analysis for lateral control system)
6.3.1 Jam
6.3.1.1 Between Wheel and PCU

Both ailerons showed movements through the whole flight. (Supported by performance; FDR Match) This condition could be ruled out
6.3.1.2 Between PCU and Aileron

Both ailerons showed movements through the whole flight. (Supported by performance; FDR Match)
This condition could be ruled out
6.3.2 Aileron PCU Hardover

Based on Performance; FDR Match + M-Cab test results, this condition could be ruled out
6.3.3 Cable Break
6.3.3.1 Between Wheel and PCU

Aileron movement in both directions noted on FDR Based on Performance; FDR Match, this condition could be ruled out

### 6.3.3.2 Between PCU and Aileron

Aileron movement in both directions noted on FDR Based on Performance; FDR Match, this condition could be ruled out
6.3.4 Trim/Feel Unit Fault
6.3.4 . 1 Aileron Trim Runaway to Approx. 25 deg.
6.3.4 . 2 Aileron Trim Runaway to 60 deg.
(See Appendix 2-1 lateral control analysis, Table 2 Hypothetical double failures scenarios (Ailerons/ Spoilers Systems), Scenario 2)

Assumptions:

- One trim switch stuck at closed position (could be a latent failure).
- Second trim switch might have stuck at closed position with trim input from the flying crew, leading to trim motor hardover position driving the ailerons to 15 degrees (maximum trim authority) towards right turn.
- This failure is assumed to occur after autopilot disconnect.
- Fault combined with pilot interference

The consequences of the hypothetical failure:

- The aileron trim actuator will reach its hardover position driving the ailerons to 15 degrees (maximum trim authority) at no load on the aileron control wheels.
- Both aileron wheels will be driven away from the neutral position. The ailerons and flight spoilers will always follow the aileron wheels. The new position for the wheel will be about 65 degrees at no load on the aileron control wheels. The force-wheels relation will change (refer to Figure 2.5.13.6 Ailerons and spoilers behavior with aileron trim actuator at its hardover position)
- Whenever the aileron wheels are released, the wheels will move to the hardover position (65 degree). The ailerons wheels will always follow each others simultaneously.
- No cockpit visual or audio warning
- The Captain and F/O will be able to resist the trim action and control the ailerons and spoilers but with additional force (Refer to Fig Figure 2.5.13.6)
- Whenever the Captain and F/O release the ailerons control wheels, the ailerons will tend to move towards right turn unless one of the flying crew exerts forces on the aileron control wheels to restore the airplane attitude

This condition could not be ruled out based on the following:

- With reference to the FDR data and after autopilot disconnect, the FDR shows tendency for the ailerons to move towards right turn direction. Movement of the aileron surfaces as shown in the FDR towards the neutral position could be explained by Captain attempts to control the airplane attitude with the existence of the failure.
- The movements of the ailerons throughout the last recovery phase highly support this scenario. The FDR data shows that even with the captain attempt to recover the airplane at the last stages, the ailerons always had the trend to move towards the opposite direction of correction which is highly consistent with the fault existence when the captain effort to restore the airplane is reduced. Forces are
higher than normal to overcome the centering springs.
- Based on evaluation in M-Cab, this event fits the data. However, trim fault must have occurred after autopilot engagement (zero force, zero aileron engagement indicates zero trim at that point).
- This hypothetical condition shows close consistency with the event. This condition is also consistent with the possibility of recovering the airplane when appropriate quantity of input is applied timely on the airplane ( $\mathrm{M}-\mathrm{Cab}$ tests).
- Consistent with Crew Behavior study

## 737-300 Lateral Control System

Figure 2.5.13.7 Ailerons and spoilers behavior with aileron trim actuator at its hardover position
6.3.5 Spoiler Fault

### 6.3.5.1 Spoiler Hardover

Based on the M- Cab results (Simulator match to FDR, Faults Simulations, results of spoilers' hardover conditions are shown hereafter), this condition shows inconsistency with the accident scenario. Therefore, this fault could be ruled out.

Figure 2.5.13.8a Right outboard flight spoilers (\#7) Hardover simulation (hardover starts at 92391) (longitudinal)

Figure 2.5.13.8b Right outboard flight spoilers (\#7) Hardover simulation (hardover starts at 92391) (lateral)

Figure 2.5.13.9a Left outboard flight spoilers (\#2) Hardover simulation (hardover starts at 92391) (Longitudinal)

Figure 2.5.13.9b Left outboard flight spoilers (\#2) Hardover simulation (hardover starts at 92391) (Lateral)

### 6.3.5.2 Spoiler Float

Based on the M- Cab results (Simulator match to FDR, Faults Simulations, results of spoilers’ float conditions are shown hereafter), this condition shows inconsistency with the accident scenario. Therefore, this fault could be ruled out.

Figure 2.5.13.10a Right outboard flight spoilers (\#7) Float simulation (floats starts at 92391) (Longitudinal)

Figure 2.5.13.10b Right outboard flight spoilers (\#7) Float simulation (floats starts at 92391) (Lateral)

Figure 2.5.13.11a Left outboard flight spoilers (\#2) Float simulation (floats starts at 92391) (Longitudinal)

Figure 2.5.13.11b Left outboard flight spoilers (\#2) Float simulation (floats starts at 92391) (Lateral)

### 6.3.5.3 Spoiler Mid-Position Jam

6.3.5.3.1 Scenario 10 - Spoiler wing cable jam (Spoiler wing cable jam) offset of the neutral position at time 92450 (maximum wheel deflection). and clears at 92472
(Refer to appendix 2-1 lateral control analysis, Table 1 Hypothetical failures scenarios (Ailerons/ Spoilers Systems), Scenario 10)

Figure 2.5.13.12 Right roll continues to overbank with ailerons activities (condition F3)

Figure 2.5.13.13 Lateral Control System

801
APR 17/85
C7.11.010

Figure 2.5.13.14 Transfer Mechanism

## Assumptions:

- The spoiler wing cable is assumed to jam offset of the neutral position at time 2:44:36 (92450 time frames in seconds). At this time the ailerons and based on the FDR data, the aileron wheels were at their maximum deflections
- The left aileron was at 8.1 degrees TED2, the right aileron was at 11.8 degrees. The airplane pitch angle was 11.25 degrees. The roll angle was 24.6 degrees (right roll)
- This fault is assumed to be cleared at 2:44:58 (92472 time frames in seconds) (beginning of the recovery effort.

Consequences of the hypothetical failure:

- The spoiler control drum will jam the lost motion device crank offset of the neutral position.
- The ailerons control wheels will, when released (no load condition) move and remain at a position equal to the position at the moment of the jam (about 40 degrees right roll-FDR data) minus 12 degrees (transfer mechanism lost motion), resulting in about 28 degree wheel deflection in the right roll direction.
- "The flight spoilers will remain in the position corresponding to the position of the jammed spoilers wing cables, irrespective of any mechanical inputs from either control wheel (about 12 degrees- FDR data). The ailerons can still be controlled via the captain's wheel. However, movement of aileron wheel towards airplane left turn (to correct for the right bank tendency) will be opposed by the override mechanism spring, consequently the forces required to move the ailerons in this direction will be significantly higher than the normal forces at no fault (about 50 lbs additional force)
- The F/O will not be able to control the ailerons in the direction of airplane left turn, with limited ability to control it in the direction of airplane right turn.
- This fault will not be associated with any visual or audio warning in the cockpit

[^39]Results of the M-Cab test3:

- During the meetings in Cairo on August 05, the MCA asked Boeing to redo simulations of scenarios 10 (spoiler cable jam) with the hypothetical fault inserted at the point of maximum wheel displacement and removed at the beginning of the recovery effort.
- Figure 2.5.13.15a (longitudinal parameters) and Figure 2.5.13.15b (lateral parameters) show the effect of the hypothetical spoiler cable jam fault.

[^40]

Figure 2.5.13.15a (longitudinal parameters)

Figure 2.5.13.15b (lateral parameters)

- The simulations take into account the effects of blowdown on the ailerons. However, the blowdown effects on the spoilers are not included because of the way in which these hypothetical faults were simulated. The effects of spoiler blowdown are not expected to be large as spoiler deflections remain below 20 degrees and airspeed during the time of the fault remains below 310 knots.
- $\quad$ The longitudinal plot (Figures Figure 2.5.13.15a) included the following parameters:
- Press Altitude (Feet)
- $\quad$ Airspeed (Knots)
- Right engine N1 (\%)
- Longitudinal acceleration (g's)
- Air/ Ground switch
- Autopilot status
- $\quad$ Pitch attitude (Degrees)
- Body angle of attack (Degrees)
- Column deflection (Degrees)
- Elevator deflection (Degrees)
- Stabilizer position (Units)
- Normal load factor (g's)
- Right main gear down
- Flap detent (Degrees)
- $\quad$ The lateral plot (Figures Figure 2.5.13.15b) included the following parameters:
- Press Altitude
- Airspeed (Knots)
- Right engine N1 (\%)
- Roll attitude (Degrees)
- Wheel force (lbs)
- Control wheel deflection (Degrees)
- Left aileron deflection (Degrees)
- Right aileron deflection (Degrees)
- Left spoiler deflection (Degrees)
- Right spoiler deflection (Degrees)
- Lateral acceleration (g's)
- Magnetic heading (Degrees)
- Rudder deflection (Degrees)
- All the parameters obtained from the M-Cab test with the fault inserted show very close consistency with the accident flight FDR data
- It is expected that wheel forces with higher magnitude can affect the speech pattern

It is noticed that there were no captain speeches when the ailerons were near to their neutral position. Most of
the speeches were made at the timing where the ailerons were moving back to their position relevant to spoilers cables jammed condition

This condition could not be ruled out, based on the following:

- A- The results obtained from the analytical studies and the M-Cab test show a close consistency with the available data.
- $\quad B$ - The airplane behavior is consistent with the consequences of the hypothetical fault:
- The ailerons movements towards airplane right roll are highly consistent with the expected position resulted from this hypothetical fault.
- This fault always drive the airplane in the right roll direction
- Movement of the aileron surfaces as shown in the FDR towards the neutral position are consistent with captain attempts to control the airplane attitude with the existence of the failure, the rate of airplane rolling to the right is always reduced with these attempts. The forces required to move the ailerons by the captain are considerably higher than the forces required in normal condition with no fault.
- Whenever the captain control wheel is released, the ailerons move towards the offset position showing high consistency with the fault existence. The fault was continually driving the airplane towards more right roll
- The movements of the ailerons throughout the last recovery phase highly support this scenario.
- In the analysis in section 2.5.11 studying the chronological event where the airplane stopped the left turn and started a right turn at about 92420, the pilot input probability was not ruled out as one of the possible causes for this event. This input might be due to temporary loss of Situational Awareness. This explains how the airplane got to the point in the right roll at which the temporary jams supposedly occurred.
- It is expected that wheel forces with higher magnitude can affect the speech pattern, however, it is noticed that there were no captain speeches when the ailerons were
near to their neutral position, most of the speeches were made at the timing where the ailerons were moving back to their position relevant to spoilers cables jammed condition. The timing and length of the Captain speeches through this event does not provide sufficient information to verify the effect of this force on the speech tone
- Crew behavior shows consistency

> - 6.3.5.3.2 Scenario 10a - F/O wheel jam (F/O wheel jam) offset of the neutral position at time 92450 (maximum wheel deflection).and clears at 92472
(Refer to appendix 2-1 lateral control analysis, Table 1 Hypothetical failures scenarios (Ailerons/ Spoilers Systems), Scenario 10a)

Assumptions:

- The F/O wheel is assumed to jam offset of the neutral position at time 2:44:36 (92450 time frames in seconds). At this time, and based on the FDR data, the aileron wheels were at their maximum deflections
- The left aileron was at 8.1 degrees TED, the right aileron was at 11.8 degrees. The airplane pitch angle was 11.25 degrees. The roll angle was 24.6 degrees (right roll)
- This fault is assumed to be cleared at 2:44:58 (92472 time frames in seconds) (beginning of the recovery effort.

Consequences of the the hypothetical failure:

- The F/O aileron control wheel will jam at a position offset of the neutral position relevant to the position of the jammed shaft.
- The ailerons control wheels will, when released (no load condition) remain at a position equal to the position at the moment of the jam (about 40 degrees right roll-FDR data). This corresponds to about 10 degrees of aileron deflections
- The flight spoilers will remain in the position corresponding to the position of the jammed spoilers wing cables (about 12 degrees- FDR data), however the captain will have a limited control on the spoilers within the transfer mechanism lost motion gap ( $\pm 12$ degree) of aileron wheel deflection. (After 12 degrees of wheel rotation, the spoiler control drum lost motion lug will contact the lost motion device crank on the F/O control wheel shaft, preventing any further movement of the spoiler control drum. The spring cartridge will compensate for the continuing inputs from the ailerons bus drums).
- The ailerons can still be controlled via the captain's wheel. However, movement of aileron wheel in
either directions will be opposed by the override mechanism spring, consequently the forces required to move the ailerons in both directions will be significantly higher than the normal forces at no fault (about 50 lbs additional force)
- The F/O will not be able to control the ailerons nor the spoilers in either direction.
- This fault will not be associated with any visual or audio warning in the cockpit

Results of the M-Cab test ${ }^{4}$ :

- Figure 2.5.13.15a (longitudinal parameters) and Figure 2.5.13.15b (lateral parameters) show the effect of the hypothetical spoiler cable jam fault.

[^41]

Figure 2.5.13.16a (longitudinal parameters)

Figure 2.5.13.16b (lateral parameters

- In this scenario, the jam restricts further motion of the spoilers to the range of the lost motion device. Figure 2.5.13.15b shows that the right wing spoilers are limited to the range of 7 to about 17 degrees and the left wing spoilers are restricted to 0 degrees. The ailerons can still be controlled via the captain's wheel. There is an immediate significant increase in wheel force as the captain must overcome the spring force of the transfer mechanism.
- Both simulations take into account the effects of blowdown on the ailerons. However, the blowdown effects on the spoilers are not included because of the way in which these hypothetical faults were simulated. The effects of spoiler blowdown are not expected to be large as spoiler deflections remain below 20 degrees and airspeed during the time of the fault remains below 310 knots.

Both figures include the wheel force required to overcome the transfer mechanism in the presence of the jam. It is significant to note that the force frequently exceeds 50 lbs .

- $\quad$ The longitudinal plot (Figure 2.5.13.16a) included the following parameters:
- Press Altitude (Feet)
- Airspeed (Knots)
- Right engine N1 (\%)
- Longitudinal acceleration (g's)
- Air/ Ground switch
- Autopilot status
- Pitch attitude (Degrees)
- Body angle of attack (Degrees)
- Column deflection (Degrees)
- Elevator deflection (Degrees)
- Stabilizer position (Units)
- Normal load factor (g's)
- Right main gear down
- Flap detent (Degrees)
- The longitudinal plot (Figure 2.5.13.16b) included the following parameters:
- Press Altitude
- $\quad$ Airspeed (Knots)
- Right engine N1 (\%)
- Roll attitude (Degrees)
- Wheel force (lbs)
- Control wheel deflection (Degrees)
- Left aileron deflection (Degrees)
- Right aileron deflection (Degrees)
- Left spoiler deflection (Degrees)
- Right spoiler deflection (Degrees)
- Lateral acceleration (g's)
- Magnetic heading (Degrees)
- Rudder deflection (Degrees)
- All the parameters obtained from the M-Cab test with the fault inserted show very close consistency with the accident flight FDR data
- It is expected that wheel forces with higher magnitude can affect the speech pattern

It is noticed that there were no captain speeches when the ailerons were near to their neutral position. Most of the speeches were made at the timing where the ailerons were moving back to their position relevant to spoilers cables jammed condition

This condition could not be ruled out, based on the following:
A. The results obtained from the analytical studies and the M-Cab test show a close consistency with the available data.
B. The airplane behavior is consistent with the consequences of the hypothetical fault:

- The ailerons movements towards airplane right roll are highly consistent with the expected position resulted from this hypothetical fault.
- This fault always drive the airplane in the right roll direction
- Movement of the aileron surfaces as shown in the FDR towards the neutral position are consistent with captain attempts to control the airplane attitude with the existence of the failure, the rate of airplane rolling to the right is always reduced with these attempts. The forces required to move the ailerons by the captain are considerably higher than the forces required in normal condition with no fault.
- Whenever the captain control wheel is released, the ailerons move towards the offset position showing high consistency with the fault existence. The fault was continually driving the airplane towards more right roll
- The movements of the ailerons throughout the last recovery phase highly support this scenario.
- In the analysis in section 2.5.11 studying the chronological event where the airplane stopped the left turn and started a right turn at about 92420, the pilot input probability was not ruled out as one of the possible causes for this event. This input might be due to momentarily loss of Situational Awareness. This explains how the airplane got to the point in the right roll at which the temporary jams supposedly occurred.
- It is expected that wheel forces with higher magnitude can affect the speech pattern, however, it is noticed that there were no captain speeches when the ailerons were near to their neutral position, most of the speeches were made at the timing where the ailerons were moving back to their position relevant to spoilers cables jammed condition. The timing and length of the Captain speeches through this event does not provide sufficient information to verify the effect of this force on the speech tone
- Crew behavior shows consistency

For the "Lateral System Fault" block, See Appendix 2-1 lateral control analysis

Cairo 4 Feb 05
13.0 Right Roll Continues to Overbank with Aileron Activity
N.B.

For the "Actuator Hardover without Force Limiter 17 to 20 lb Force (SCENARIO 11)" block, See Appendix 2-1 lateral control analysis

Aileron movement in both directions noted on FDR

Evalutation in M-Cab fits data.
However, trim fault must have occurred after autopilot engagement (zero force, zero aileron engagement indicates zero trim at that point).

Review ROV videos for trim actuator.

### 2.5.14 Flight crew CVR autopilot announcements

The following Figure shows the related FDR and CVR events

Figure 2.5.14.1 Flight crew CVR autopilot announcements

Flight crew CVR autopilot announcements might be explained by the following ${ }^{1}$ :

1. Requests for Autopilot Engagement

This scenario is consistent with expected normal airplane operation. If the Captain asked for autopilot and the F/O pressed the CMD button, the interlocks would not be satisfied because of forces on the control wheel. In this case, the button push is not recorded as an autopilot engagement on the FDR.
(Done on M-Cab)
2. Announcement of Autopilot Status (Announcement of "Autopilot in Command" made by the F/O):

This might be explained by one of the following possibilities:

1. The statement was made automatic on button push without confirmation
2. F/O thought autopilot was engaged
3. F/O made mistake
4. Announcement of "No autopilot commander" made by the F/O:

This announcement indicates that the F/O believed, to at least mean, that autopilot was not currently in operation.
4. Announcement of Perceived Autopilot Behavior
5. Requests for Autopilot Disengagement

This condition requires perception on the part of the Captain that the autopilot is engaged

It is to be noticed that similar crew announcement occur during autopilot engagement near wings level. The evaluation of the comments here should take into account the meaning of the earlier announcements.

The investigation could not determine a higher possibility to any of the above conditions based on the given data.

[^42]

### 2.5.15 Rapid left roll towards wings level

The following figure shows the related FDR and CVR data

Figure 2.5.15 Rapid left roll towards wings level

The possibilties for this event are as follows:

1- Captain Upset Recovery Attempt
Captain Input Only
Captain in Presence of System Fault
This condition is supported by the information that the Captain was the pilot flying with nothing on CVR to suggest that control was transferred.
(Refer to section 2.6 Human Behavior, CBS report regarding CVR comments.)
2- First Officer Upset Recovery Attempt
First Officer Input Only
First Officer in Presence of System Fault
Based on CVR information, the FO did not announce that he is taking control.
(Refer to section 2.6 Human Behavior, CBS report regarding CVR comments.)

3- Joint Upset Recovery Attempt
Crew Input Only (Captain, F/O, \& Observer)
Crew in Presence of System Fault (Captain, F/O, \& Observer)
It is to be noted that previous upset events have resulted in multiple crew making control inputs; however the F/O does not announce he is taking control.

4- Lateral System Fault
PCU Fault
Based on the FDR data, the aileron motion recorded in both directions, even during recovery

AP Actuator Fault
The aileron was commanded beyond A/P actuator limit (60 degrees of aileron wheel)

5- AP engaged and provided roll input
The aileron was commanded beyond A/P authority limit (17 degrees of aileron wheel)

Note:
Initiation of this event is coincident with announcement of "No autopilot commander"

Conditions 4 and 5 might be ruled out.
From the above, Captain Upset Recovery Attempt seems a higher possibility

Updated: 10/1/04 (Seattle)

### 2.5.16 Impact with water

The impact occurred at about 92480 (02:45:06 GMT) with the following conditions:

| Bank Angle | $24.6^{\circ}$ to the right |
| :--- | :--- |
| Pitch Angle | $24^{\circ}$ Nose down |
| Vertical G. <br> Load | 3.9 |
| Speed | 416 Kts |

Although an attempt to correct the recovery was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

## Appendix 2-1 lateral control system analysis

Lateral Control System analysis:
The following table contains several hypothetical failure scenarios within the ailerons and spoilers control systems. The table also shows the consequences of the failures and the ability to control the airplane from either pilot's side.
The objective of this analysis is to exclude all the hypothetical failure scenarios that will not lead to the event (aileron movement causing airplane Overbank, with recorded aileron movements in both directions) and consider the other remaining failure scenarios which could lead to the event.

Table 1: Hypothetical single failures scenarios (Ailerons/ Spoilers Systems)

| Ser. | Failed Component | Type of Failure | Input from Captain | Input from F/O |  |
| :---: | :---: | :---: | :---: | :---: | :---: |

Appendix 2-2 Studies of other airplane incidents relevant to autoflight systems

Two cases of malfunctions related to Boeing 737-500 autopilot system were reported by one operator as follows:

## I- CASE of "AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT"

## 1- BOEING REPLY, EXCESSIVE RATE OF DESCENT 11/8/2004 2:25:33 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

One Operator reports that during descent with A/P A engages, VS mode selected and 1500 FPM selected on MCP panel airplane started a descent with a rate of 3000 FPM. Crew reported that this occurred two times. Crew reported that A/P operated normal.

Maintenance reported the following AFDS Bite results:
Possible Causes
Stab Trim M255
Elevator Pos. Sensor
Stab. Pos. Sen-1
Attached for review is DFDR data for the flight which started at 2000 GMT and ended at 2110 GMT.

## ACTION:

The operator requests that Boeing review the submitted DFDR data and advise findings.

## 2. BOEING REPLY, EXCESSIVE RATE OF DESCENT

## 11/21/2004 2:55:20 AM PST

[MESSAGE NUMBER: 1-STLI4]
FROM: THE BOEING COMPANY

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /A/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. Boeing would be interested in knowing the altitude that was selected during the event and at what altitude the capture maneuver was initiated. Any available FDR data may be helpful in reviewing this event.

Regarding the A/P bite faults, Boeing would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an operator mechanic while in the flight deck of the airplane.

Please advise if the operator can support further troubleshooting using a cell phone in the flight deck where the FCC BITE can be performed via telecon with Boeing. If affirmative, please provide a time and phone number that Boeing can contact.

As reported previously, the operator has performed adjustments of the Ref /D/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Datum airplane is currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref /D/ rods.

## ACTION:

Please review and advise if Boeing concurs with the operator on replacement of the Ref /D/ rods.

## 3- BOEING REPLY, EXCESSIVE RATE OF DESCENT 23-Nov-2004 11:42:51 AM PST

## [SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /A/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. In addition, Boeing advised we would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an the operator mechanic while in the flight deck of the airplane.

As reported previously, the operator has performed adjustments of the Ref /D/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Datum airplane is currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref /D/ rods.

ACTION:
Please review and advise if Boeing concurs with the operator on replacement of the Ref /D/ rods.

RESPONSE:
Last night, Boeing engineering was able to contact the operator personnel who were in the flight deck of the datum airplane. Based on the BITE tests performed and discussions with the operator personnel, it was decided that replacement of both of the A/P elevator actuator rod assemblies (shown in Figure 401 on page 402 of AMM 22-1126) is the next maintenance action to be taken. Following replacement, the Autopilot Elevator Actuator Adjustment (DFCS BITE Test) (TASK 22-11-26-825-047) must be performed (AMM 22-11-26/501). Note, when installing the rod assembly between the two actuators, the operator needs to tighten the locknuts and lock wire in place on the end.

23-Nov-2004 11:42:51 AM PST

4- BOEING REPLY, EXCESSIVE RATE OF DESCENT
11/30/2004 4:07:08 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /C/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. In addition, Boeing advised they would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an operator mechanic while in the flight deck of the airplane. As reported previously, the operator has performed adjustments of the Ref /E/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Ref/B/ advised that datum airplane was currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref/F/ rods.

On 22-Nov-2004, Boeing engineering was able to contact the operator personnel who were in the flight deck of the datum airplane. Ref /A/ advised that based on the BITE tests performed and discussions with the operator personnel, it was decided that replacement of both of the A/P elevator actuator rod assemblies (shown in Figure 401 on page 402 of AMM 22-11-26) is the next maintenance action to be taken. Following replacement, the Autopilot Elevator Actuator Adjustment (DFCS BITE Test) (TASK 22-11-26-825-047) must be performed (AMM 22-11-26/501). Note, when installing the rod assembly between the two actuators, the operator needs to tighten the locknuts and lock wire in place on the end.

The operator replaced and adjusted the Ref /F/ rods and released the airplane for service. On 26-Nov-2004 the crew reported that, with A/P "A" engaged and V/S of 2000 FPM selected, aircraft descent was 4,000 FPM. See attached log sheet for details. On 28-Nov-2004, crew reported that with A/P "A" engaged MCP ALT 33,000, FMA- ALT ACQ the airplane started a descent of more than 2000 FPM. Please see attached log sheet for details. Aircraft is currently operating using A/P "B" only.

Attached for review is DFDR data for the 26 -Nov event flight leg. As reported above, the reported excessive descent rate was during descent.

The operator is requesting that Boeing review the data and report findings. The operator management has also requested on-site technical assist.

ACTION:

1. Please review the attached DFDR data and report findings.
2. Please advise if Boeing can provide on-site technical assist.

A response by 01-Dec is requested.

## 5- BOEING REPLY, EXCESSIVE RATE OF DESCENT

01-Dec-2004 01:52:43 PM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /C/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. In addition, Boeing advised they would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an the operator mechanic while in the flight deck of the airplane. As reported previously, the operator has performed adjustments of the Ref /F/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Ref/B/ advised that datum airplane was currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref/F/ rods.

On 22-Nov-2004, Boeing engineering was able to contact the operator personnel who were in the flight deck of the datum airplane. Ref /A/ advised that based on the BITE tests performed and discussions with the operator personnel, it was decided that replacement of both of the A/P elevator actuator rod assemblies (shown in Figure 401 on page 402 of AMM 22-11-26) is the next maintenance action to be taken. Following replacement, the Autopilot Elevator Actuator Adjustment (DFCS BITE Test) (TASK 22-11-26-825-047) must be performed (AMM 22-11-26/501). Note, when installing the rod assembly between the two actuators, the operator needs to tighten the locknuts and lock wire in place on the end.

The operator replaced and adjusted the Ref /F/ rods and released the airplane for service. On $26-$ Nov-2004 the crew reported that, with A/P "A" engaged and V/S of 2000 FPM selected, aircraft descent was 4,000 FPM. See attached log sheet for details. On 28-Nov-2004, crew reported that with A/P "A" engaged MCP ALT 33,000, FMA- ALT ACQ the airplane started a descent of more than 2000 FPM. Please see attached log sheet for details. Aircraft is currently operating using A/P "B" only.

Attached for review is DFDR data. As reported above, the reported excessive descent rate was during descent into SSH.

The operator is requesting that Boeing review the data and report findings. The operator management has also requested on-site technical assist.

ACTION:

1. Please review the attached DFDR data and report findings.
2. Please advise if Boeing can provide on-site technical assist.

Reply:
Boeing has reviewed the provided FDR data and pilot reports. During the event, the elevator was out of nose up elevator authority while A was engaged, however no trim
commands were output by A to pitch the airplane nose up. Four seconds after B was engaged (elevator remained where it was) the stab drove for about 6 seconds which relieved the elevator about 1 degree. There were other times in the data where A did command trim in both directions, so FCC A was capable of trim.

Boeing would recommend the following troubleshooting to verify the FCC stab trim interface as well as verification of the elevator position input to the channel A FCC:

Perform the DFCS Chapter 22 BITE Stab Trim rigging test, Elevator Rigging test (Both Single Authority and Dual Authority tests) and Mach Trim Rigging test. Verify that all the readings for these tests are within limits. As needed, Boeing will be available to support these checks by telecon. Please advise if the operator requests Boeing assistance by telephone during these checks and provide a contact time and number.

The noted condition could also be due to an incorrect FCC calculation of autopilot elevator authority upon which the trim thresholds are based. This calculation uses inputs from the ADCs. To help isolate this possible condition, we would recommend the operator swapping the left and right ADCs and IRUs.

## 6- BOEING REPLY, EXCESSIVE RATE OF DESCENT 03-Dec-2004 03:38:20 PM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

This is to advise that Boeing has reviewed the FCC BITE data provided in fax dated 3 December and the data indicates all test results passed and FCC operation appears normal. Therefore Boeing has no further recommendations at this time and recommends using both $A$ and $B$ channel autopilots. In the event the condition occurs again, please provide a listing of any DFCS in flight faults, FCC Bite test results for elevator and stab rigging checks and FDR data for review.

## 7- BOEING REPLY, EXCESSIVE RATE OF DESCENT:

 12/6/2004 5:56:58 AM PST
## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to Ref /D/, Ref /C/ advised that Boeing had reviewed the provided FDR data and pilot reports. During the event, the elevator was out of nose up elevator authority while A was engaged, however no trim commands were output by A to pitch the airplane nose up. Four seconds after B was engaged (elevator remained where it was) the stab drove for about 6 seconds which relieved the elevator about 1 degree. There were other times in the data where A did command trim in both directions, so FCC A was capable of trim.

Boeing recommended the following troubleshooting to verify the FCC stab trim interface as well as verification of the elevator position input to the channel A FCC:

Perform the DFCS Chapter 22 BITE Stab Trim rigging test, Elevator Rigging test (Both Single Authority and Dual Authority tests) and Mach Trim Rigging test. Verify that all the readings for these tests are within limits. As needed, Boeing will be available to support these checks by telecon. Please advise if the operator requests Boeing assistance by telephone during these checks and provide a contact time and number.

The noted condition could also be due to an incorrect FCC calculation of autopilot elevator authority upon which the trim thresholds are based. This calculation uses inputs from the ADCs. To help isolate this possible condition, we would recommend the operator swapping the left and right ADCs and IRUs.

Ref /B/ provided results of the above recommended tests.
Ref /A/ advised that Boeing had reviewed the FCC BITE data provided in fax dated 3 December and the data indicates all test results passed and FCC operation appears normal. Therefore Boeing has no further recommendations at this time and recommends using both $A$ and $B$ channel autopilots. In the event the condition occurs again, please provide a listing of any DFCS in flight faults, FCC Bite test results for elevator and stab rigging checks and FDR data for review. The operator has reviewed the Ref /A/ and /C/ responses and is requesting clarification regarding the intermittent trim command output from FCC A. As reported above, the elevator was out of nose up elevator authority while A was engaged, however no trim commands were output by A to pitch the airplane nose up. It was also verified that there were other times in the data where A did command trim in both directions, so FCC A was (is) capable of trim.

The operator is requesting further Boeing recommendations and on-site tech assist.

## ACTION:

1. Based on the above data is replacement of the FCC A horizontal position sensor and sensor wiring check recommended?
2. Based on the above data, is an intermittent circuit between FCC A D1671B, pin 42, wire 102-20 to splice SP3677 a possible cause of the intermittent trim UP command?
3. Please advise any additional wiring checks to be performed.

Commercial Aviation Services

8- BOEING REPLY, EXCESSIVE RATE OF DESCENT:
09-Nov-2004 03:42:22 PM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

The operator reports that, during descent with A/P A engages, VS mode selected and 1500 FPM selected on MCP panel airplane started a descent with a rate of 3000 FPM. Crew reported that this occurred two times. Crew reported that A/P operated normal.

Maintenance reported the following AFDS Bite results:
Possible Causes
Stab Trim M255
Elevator Pos. Sensor
Stab. Pos. Sen-1
Attached for review is DFDR data for the flight.

## ACTION:

The operator requests that Boeing review the submitted DFDR data and advise findings.
Reply,
Boeing has reviewed the FDR data and we do not identify any unusual autopilot operation noted in the reviewed data. The selected V/S is not recorded and therefore it is difficult to determine how well the autopilot is tracking vertical speed. We produced a derivative of the airplane altitude to determine where in the flight the vertical speed was 3000 feet per minute or greater. The resulting vertical speed data plot did not confirm any flight segment that exhibited a vertical speed of 3000 feet per minute or greater. As an added note, if the winds change with altitude, the airplane vertical speed will be upset in the short term from that selected.

Commercial Aviation Services
The Boeing Company

Ref /B/ provided results of the above recommended tests.
Ref /A/ advised that Boeing had reviewed the FCC BITE data provided in fax dated 3 December and the data indicates all test results passed and FCC operation appears normal. Therefore Boeing has no further recommendations at this time and recommends using both $A$ and $B$ channel autopilots. In the event the condition occurs again, please provide a listing of any DFCS in flight faults, FCC Bite test results for elevator and stab rigging checks and FDR data for review. the operator has reviewed the Ref /A/ and /C/ responses and is requesting clarification regarding the intermittent trim command output from FCC A. As reported above, the elevator was out of nose up elevator authority while A was engaged, however no trim commands were output by A to pitch the airplane nose up. It was also verified that there were other times in the data where A did command trim in both directions, so FCC A was (is) capable of trim.

The operator is requesting further Boeing recommendations and on-site tech assist.

## ACTION:

1. Based on the above data is replacement of the FCC A horizontal position sensor and sensor wiring check recommended?
2. Based on the above data, is an intermittent circuit between FCC A D1671B, pin 42, wire 102-20 to splice SP3677 a possible cause of the intermittent trim UP command?
3. Please advise any additional wiring checks to be performed.

Reply:
The stab position data is used in determining trim thresholds. We also agree that an open between FCC A D1671B pin 42 would result in the A channel FCC being unable to command a trim up. Therefore, replacement of the stab position sensor and sensor wire verification is recommended.

We understand that the airplane has returned to service and we have no further recommendations at this time.

## 10- BOEING REPLY, EXCESSIVE RATE OF DESCENT: 12/13/2004 6:06:11 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

Refs /A/ thru /E/ discuss subject events and troubleshooting accomplished by the operator and Boeing recommendations.

Pilot reported the following: "During descent to FL160, A/P "A" engaged, FMA displayed ALT ACQUIRE but airplane continued descent." Airplane returned with A/P "B" engaged and no faults were noted. Airplane has been operating using A/P "B".

The operator has provided the attached DFDR data for the event. Please note the altitude reported above may be 1,600 feet vs FL160.

The airplane is currently out of service for troubleshooting.
ACTION:
The operator requests that Boeing review the attached DFDR data and advise findings.

## 11- BOEING REPLY, EXCESSIVE RATE OF DESCENT: <br> 13-Dec-2004 11:06:19 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

Refs /A/ thru /E/ discuss subject events and troubleshooting accomplished by the operator and Boeing recommendations.

Pilot reported the following: "During descent to FL160, A/P "A" engaged, FMA displayed ALT ACQUIRE but airplane continued descent." Airplane returned with A/P "B" engaged and no faults were noted. Airplane has been operating using A/P "B".

The operator has provided the attached DFDR data for the event. Please note the altitude reported above may be 1,600 feet vs FL160.

The airplane is currently out of service for troubleshooting.

## ACTION:

the operator requests that Boeing review the attached DFDR data and advise findings.
RESPONSE:
For this event, it appears that when ALT ACQUIRE was engaged the elevator moved about 1 degree to slow the rate of descent and then remained flat at that value for the 10 seconds it was in the mode. It appears there was not enough elevator authority on the A side to finish pitching the airplane up, and it continued to slowly pitch down until the autopilot was disconnected.

Also during the acquire, the autopilot was not trimming the stabilizer. Since the flaps were at 1, the autopilot trims based on elevator position. Therefore, the autopilot probably could not move the quadrant far enough. Based on this and the previous event, it would appear that the A actuator does not have the required authority, for whatever reason.

## II- CASE of AUTOPILOT OVERBANK

1- Case of Overbank Follow up:
Model: 737-500

## Pilot Report:

During Departure with LNAV engaged, when selecting $A / P$ " $B$ ", $A / P$ " $B$ " engaged then disengaged. After satisfying F/D again A/P selected then autopilot gives more than 35 deg. bank angle and increasing. A/P disconnected again followed by F/D Pitch bar out of view. F/D switches recycled off-on.

After Flap retraction and with aircraft was leveled A/P selected again operates normally ( A \& $B$ )

Maintenance Action:

- Autoflight system checked on ground from MCDU according to M.M. found operating normal.
- Last flight faults checked, found no faults recorded.
- Both IRS checked found OK
- Flight data recorder removed for read out and aircraft released for flight.
- Snag not repeated on the next flights but FDR read out for the subject flight shows that autopilot exceeds bank angle limitation.
- A/P "B" was deactivated and considered A/P "B" D. Defect according to MEL.
N.B

The airplane has a history in flight control problems, Boeing have the full details.
(Subject Flight FDR raw data available if needed)

Please do not reply. This message is the acknowledgement of your request.
Your Service Request has been received by The Boeing Company. Your request will be reviewed and a response provided in accordance with your request. Thank you for your inquiry.

## SUBJECT: Autopilot Overbank / DESCRIPTION:

T he flight crew reported the following:
During departure with LNAV engaged, AP "B" selected, the AP "B" engaged then disengaged. After satisfying F/D, again AP selected. At UTC 20:14 the autopilot gave more than 35 degree bank angle and increased. A/P disconnected followed by F/D pitch bar out of view, F/D switches recycled. Flap retraction and leveled, AP selected and operation normal.

Maintenance Action:
the operator maintenance checked on ground Autopilot system from MCDU and per MM no findings. Both IRS checked no finding. FDR removed for analysis and plane released back on flight line. Snag didn't reappear on the next flight. According to FDR the subject airplane had an autopilot exceeds bank angle limitations.
The operator deactivated the AP "B" and considered the AP "B" defected according to MEL.
The FDR raw data is available for Boeing review if required.
Action:
The airplane has a history of heavy flight control per Ref /A/ SR.
The subject Airplane is currently AOG for troubleshooting.
Please review the above information and advise the operator with any recommended troubleshooting.

SUBJECT: Autopilot Overbank /
DESCRIPTION:
The flight crew reported the following:
During departure with LNAV engaged, AP "B" selected, the AP "B" engaged then disengaged. After satisfying F/D, again AP selected. At UTC 20:14 the autopilot gave more than 35 degree bank angle and increased. A/P disconnected followed by F/D pitch bar out of view, F/D switches recycled. Flap retraction and leveled, AP selected and operation normal.

Maintenance Action:
the operator maintenance checked on ground Autopilot system from MCDU and per MM no findings. Both IRS checked no finding. FDR removed for analysis and plane released back on flight line. Snag didn't reappear on the next flight. According to FDR the subject airplane had an autopilot exceeds bank angle limitations.

The operator deactivated the AP "B" and considered the AP "B" defected according to MEL.
The FDR raw data is available for Boeing review if required.

## ACTION:

The airplane has a history of heavy flight control per Ref /A/ SR.
The subject Airplane is currently AOG for troubleshooting.
Please review the above information and advise the operator with any recommended troubleshooting.

As a follow-up, the operator attached the FDR data to Message Number: 1-1A4J4N.
RESPONSE:

We have analyzed the flight data recorder data provided by the operator, and are providing that analysis, followed by troubleshooting suggestions. The figures referred to in the analysis are provided as attachments to this response.

FDR Analysis

Analysis of the FDR data indicate that the overbank resulted when the pilot released the wheel, possibly to engage the autopilot, while the airplane had been trimmed with approximately 1.5 degrees of nose-left rudder pedal. Figure 1 presents the lateral and directional data for the event; for reference, the longitudinal parameters during the event are provided in Figure 2, although they did not play a significant role in the overbank.

The airplane performed a flaps 5 takeoff, becoming airborne at time 546 according to the air/ground logic. The airplane climbed out at 160 KCAS and shortly after lift off initiated a left turn from heading 295 towards heading 170. The wind was out of heading 050, increasing to about 25 knots in the air - this would constitute a quartering right tailwind transitioning to a quartering left tailwind. Note that FDR wind data are not valid on the ground.

At liftoff, the control wheel was deflected to about 25 degree right, and held at that deflection to maintain wings level. As the left turn was initiated, wheel was relaxed back to neutral and then deflected slightly left. At time 570 the wheel was relaxed to neutral and the A/P "B" was engaged - at this time the airplane had zero control wheel displacement but was rolling left at about 2.5 deg/sec. After about 1 sec , the A/P "B" disengaged. The control wheel was then deflected to the right, again to about 25 degrees, and arrested the roll at 30 degrees of left bank. At time 592 the control wheel returned to neutral and the A/P "B" channel was engaged again. As the wheel returned to neutral, the airplane again began to roll left at about 2 deg $/ \mathrm{sec}$. At time 597 the A/P " B " disengaged a second time and the CWS ROLL discrete (not shown) briefly engaged for 1 frame. Control wheel was deflected to 40 degrees right, the bank angle returned to zero and then continued right to about 4 degrees, then wheel was relaxed back to about 20 degrees right to hold bank angle between 5-8 degrees right.

During the entire event, from liftoff to the CWS engage and the roll back to 5-8 degrees right, the airplane appears to have been in a small nose-left sideslip. Rudder pedal indicates about 1.5 degrees nose left, and rudder position indicates about 2.7 degrees nose left. Furthermore, lateral acceleration persisted throughout the event at about -. 03 g 's, another indication of small sideslip angle. A simulation of the event confirms that, for the airspeed, altitude, and airplane configuration, a rudder pedal input of 1.5 degrees would give about 2.7 degrees of rudder and would require about 26 degrees of right wheel to balance. As the airspeed increased (FDR time 605 and on) the rudder blew down, and the amount of wheel required to balance reduced to about 20 degrees.

Figure 3 shows the takeoff roll. At time 505, the engines began to spool up - prior to this, the rudder pedal and rudder position parameters are both very close to zero (neutral). Shortly afterwards, several large pedal and rudder deflections occurred, accompanied by changes in heading. This is not unusual at the beginning of a takeoff roll and generally indicates that the pilot was aligning the aircraft on the runway centerline. By time 530 the rudder pedal deflections had subsided, but the rudder pedal position remained approximately at 1-2 degrees nose-left. The reason for this is unknown, but the deflection of pedal is confirmed by the accompanying rudder deflection of approximately 2-3 degrees nose left.

Figure 4 shows the FDR data after the event. At time 690, the flaps had been retracted to UP, and the airplane was just completing a left turn to heading 170, with bank angle returning to neutral. At this time, the pedal remained deflected at 1.3 degrees nose left, the rudder position was 2.2 degrees nose left, and 20 degrees of right wheel were required to hold the wings level. At this airspeed (now 205 KCAS) the simulation again indicates that this is consistent. As airspeed began increasing toward 250 KCAS, the rudder pedal and rudder position slowly neutralized; this was likely the result of manual trim adjustments by the crew, as the rudder appears to return in steps similar to the trim rate (note the expanded scale on rudder pedal on Figure 4). During the descent, as airspeed increased, the data indicate that the rudder pedal and rudder position remained
near neutral, further suggesting that the situation was corrected during the cruise.
Conclusion
----------

The FDR data indicate that PT561 experienced an overbank during an attempted autopilot engage because the airplane was in a small nose-left sideslip as the result of rudder pedal being deflected to approximately 1.5 degrees nose left. The reasons for this are unknown and cannot be determined from the FDR data, but the trim likely arose either from crew trim inputs during the takeoff roll (possibly inadvertent) or from something sticking in the rudder feel and centering unit. The simulation confirms that the sideslip resulting from the pedal input would have required approximately 25 degrees of right control wheel deflection to maintain wings level flight, as indicated by the FDR data. During each attempt to engage the " B " autopilot, the wheel was released to neutral and the airplane rolled at between 2 and $2.5 \mathrm{deg} / \mathrm{sec}$ as a result of the sideslipinduced roll.

Past experience with lateral trim issues on 737 's would indicate that flap rigging was not a factor, as the roll that can be produced by flap mis-rigging is not nearly large enough to require 25 degrees of control wheel. Small sideslip angles, on the other hand, can produce significant roll asymmetries.

From the data provided, the autopilot was working normally.
We suggest that the operator accomplish the following troubleshooting:

- Do a test of the rudder centering

AMM 27-21-00 Task S 735-012-001

- Do a test of the rudder pedal forces

AMM 27-21-00 Task S 735-014-001

- Do the rudder trim control system test

AMM Task 27-21-00-735-22-001
If any of the above tests are unsatisfactory, visually inspect the rudder feel and centering unit cam roller bearing to verify whether it is rolling on the cam when the rudder pedals are moved. If it is sliding on the cam instead of rolling, the bearing must be replaced.

4- Case of Overbank Follow up:
(Autopilot Overbank
29-03-05.
Dear Sir,
With refer to Boeing "MESSAGE NUMBER:1-1A7XEW", Required rudder tests in process. The operator notices that at 20:15:47, FDR data shows the follow:

Aircraft Roll 34.81
A/P "B" In Command
A/P Roll Mode LNAV
And with all previous condition autopilot still engaged till autopilot disconnected by the captain one second later.

Request:
Boeing Recommendation for the above situation.

5- BOEING COMPANY REPLY, 30-Mar-2005 02:01:38 PM PST

The operator has reviewed the FDR readout summary. The operator notes that FDR data point at time 20:15:47 reads:

```
Aircraft Roll 34.81
A/P "B" In Command
A/P Roll Mode LNAV
and with previous condition autopilot still engaged until disconnected by the
captain one second later.
```

The operator also notes that the autopilot usually limits roll to approximately 30 degrees while engaged. The operator requests additional explanation regarding the recorded roll angle of 34.81 with the A/P engaged and LNAV selected.

Action:

1) Please review the aforementioned query and provide an explanation.
2) Please advise if any additional troubleshooting is required other than that provided in Activity 1-1A7XEW.

## Reply:

Attached is an expanded plot of this event. The autopilot doesn't couple to the surface at the instant it is engaged. It first synchronizes the LVDT in the actuator to the surface position sensor in the quadrant. Also, FDR data is not sampled often enough to be sure of the exact timing; however it is probably the case that the detent solenoid that couples the autopilot to the surface was not actuated until the roll had already reached the maximum bank angle recorded. (The autopilot was engaged after the airplane had already established a roll rate to increase the bank angle to greater than 30 deg ). In addition, for this engagement, the initial data point for CMD occurred just prior to the control wheel reaching zero. Since the surface was moving at the time of engagement, synchronization to that surface would take somewhat longer than normal.

We do not have any additional troubleshooting recommendations regarding this event.

DESCRIPTION:
The following information has been received from the operator in response to Boeing request for flight fault information:
//QUOTE//As the aircraft return, the Captain on command recorded his report in the T.
Log Book, Autoflight was checked from FMC CDU using codes 100 and 300. No recorded faults found. Again after ur. email was received autoflight checked using codes 100 and 300 on 7th of April, 05 found one fault was recorded on flt -1 as follow * ERROR FCC-B* P2 P SPM TRIP B-8776 A/P DISC.

Nothing else was recorded.//UNQUOTE//

## ACTION:

Please review and advise if Boeing has any additional comments on the subject event or any additional troubleshooting/maintenance recommendations.

Reply:
The Bite fault note on 7 April is most likely not related to the event dated 19 March because the FCC will retain faults for only 9 flight legs.

The BITE message indicates the FCC recorded an internal fault. Also, the ERROR FCC-B indicates the fault was logged while the FCC was in the B channel and this computer was subsequently swapped to the A side when the BITE was interrogated.

Appendix 2-2 Studies of other airplane incidents relevant to autoflight systems

Two cases of malfunctions related to Boeing 737-500 autopilot system were reported by one operator as follows:

## I- CASE of "AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT"

## 1- BOEING REPLY, EXCESSIVE RATE OF DESCENT 11/8/2004 2:25:33 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

One Operator reports that during descent with A/P A engages, VS mode selected and 1500 FPM selected on MCP panel airplane started a descent with a rate of 3000 FPM. Crew reported that this occurred two times. Crew reported that A/P operated normal.

Maintenance reported the following AFDS Bite results:
Possible Causes
Stab Trim M255
Elevator Pos. Sensor
Stab. Pos. Sen-1
Attached for review is DFDR data for the flight which started at 2000 GMT and ended at 2110 GMT.

## ACTION:

The operator requests that Boeing review the submitted DFDR data and advise findings.

## 2. BOEING REPLY, EXCESSIVE RATE OF DESCENT

## 11/21/2004 2:55:20 AM PST

[MESSAGE NUMBER: 1-STLI4]
FROM: THE BOEING COMPANY

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /A/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. Boeing would be interested in knowing the altitude that was selected during the event and at what altitude the capture maneuver was initiated. Any available FDR data may be helpful in reviewing this event.

Regarding the A/P bite faults, Boeing would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an operator mechanic while in the flight deck of the airplane.

Please advise if the operator can support further troubleshooting using a cell phone in the flight deck where the FCC BITE can be performed via telecon with Boeing. If affirmative, please provide a time and phone number that Boeing can contact.

As reported previously, the operator has performed adjustments of the Ref /D/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Datum airplane is currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref /D/ rods.

## ACTION:

Please review and advise if Boeing concurs with the operator on replacement of the Ref /D/ rods.

## Commercial Aviation Services

## 3- BOEING REPLY, EXCESSIVE RATE OF DESCENT 23-Nov-2004 11:42:51 AM PST

## [SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /A/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. In addition, Boeing advised we would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an the operator mechanic while in the flight deck of the airplane.

As reported previously, the operator has performed adjustments of the Ref /D/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Datum airplane is currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref /D/ rods.

ACTION:
Please review and advise if Boeing concurs with the operator on replacement of the Ref /D/ rods.

RESPONSE:
Last night, Boeing engineering was able to contact the operator personnel who were in the flight deck of the datum airplane. Based on the BITE tests performed and discussions with the operator personnel, it was decided that replacement of both of the A/P elevator actuator rod assemblies (shown in Figure 401 on page 402 of AMM 22-1126) is the next maintenance action to be taken. Following replacement, the Autopilot Elevator Actuator Adjustment (DFCS BITE Test) (TASK 22-11-26-825-047) must be performed (AMM 22-11-26/501). Note, when installing the rod assembly between the two actuators, the operator needs to tighten the locknuts and lock wire in place on the end.

23-Nov-2004 11:42:51 AM PST

4- BOEING REPLY, EXCESSIVE RATE OF DESCENT
11/30/2004 4:07:08 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /C/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. In addition, Boeing advised they would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an operator mechanic while in the flight deck of the airplane. As reported previously, the operator has performed adjustments of the Ref /E/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Ref/B/ advised that datum airplane was currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref/F/ rods.

On 22-Nov-2004, Boeing engineering was able to contact the operator personnel who were in the flight deck of the datum airplane. Ref /A/ advised that based on the BITE tests performed and discussions with the operator personnel, it was decided that replacement of both of the A/P elevator actuator rod assemblies (shown in Figure 401 on page 402 of AMM 22-11-26) is the next maintenance action to be taken. Following replacement, the Autopilot Elevator Actuator Adjustment (DFCS BITE Test) (TASK 22-11-26-825-047) must be performed (AMM 22-11-26/501). Note, when installing the rod assembly between the two actuators, the operator needs to tighten the locknuts and lock wire in place on the end.

The operator replaced and adjusted the Ref /F/ rods and released the airplane for service. On 26-Nov-2004 the crew reported that, with A/P "A" engaged and V/S of 2000 FPM selected, aircraft descent was 4,000 FPM. See attached log sheet for details. On 28-Nov-2004, crew reported that with A/P "A" engaged MCP ALT 33,000, FMA- ALT ACQ the airplane started a descent of more than 2000 FPM. Please see attached log sheet for details. Aircraft is currently operating using A/P "B" only.

Attached for review is DFDR data for the 26 -Nov event flight leg. As reported above, the reported excessive descent rate was during descent.

The operator is requesting that Boeing review the data and report findings. The operator management has also requested on-site technical assist.

ACTION:

1. Please review the attached DFDR data and report findings.
2. Please advise if Boeing can provide on-site technical assist.

A response by 01-Dec is requested.

## 5- BOEING REPLY, EXCESSIVE RATE OF DESCENT

01-Dec-2004 01:52:43 PM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to the subject report, Ref /C/ advised that is possible that hysterisis in the actuator linkage can result in poor autopilot control. In addition, Boeing advised they would like to arrange for a convenient time when we could contact the operator and walk through some BITE tests with an the operator mechanic while in the flight deck of the airplane. As reported previously, the operator has performed adjustments of the Ref /F/ rods numerous times. After adjustment the aircraft would fly for a few days with no write-ups for the subject fault.

Ref/B/ advised that datum airplane was currently operating under MEL for A/P system A. Based on previous experience with this airplane, the operator is investigating whether to change the Ref/F/ rods.

On 22-Nov-2004, Boeing engineering was able to contact the operator personnel who were in the flight deck of the datum airplane. Ref /A/ advised that based on the BITE tests performed and discussions with the operator personnel, it was decided that replacement of both of the A/P elevator actuator rod assemblies (shown in Figure 401 on page 402 of AMM 22-11-26) is the next maintenance action to be taken. Following replacement, the Autopilot Elevator Actuator Adjustment (DFCS BITE Test) (TASK 22-11-26-825-047) must be performed (AMM 22-11-26/501). Note, when installing the rod assembly between the two actuators, the operator needs to tighten the locknuts and lock wire in place on the end.

The operator replaced and adjusted the Ref /F/ rods and released the airplane for service. On $26-$ Nov-2004 the crew reported that, with A/P "A" engaged and V/S of 2000 FPM selected, aircraft descent was 4,000 FPM. See attached log sheet for details. On 28-Nov-2004, crew reported that with A/P "A" engaged MCP ALT 33,000, FMA- ALT ACQ the airplane started a descent of more than 2000 FPM. Please see attached log sheet for details. Aircraft is currently operating using A/P "B" only.

Attached for review is DFDR data. As reported above, the reported excessive descent rate was during descent into SSH.

The operator is requesting that Boeing review the data and report findings. The operator management has also requested on-site technical assist.

ACTION:

1. Please review the attached DFDR data and report findings.
2. Please advise if Boeing can provide on-site technical assist.

Reply:
Boeing has reviewed the provided FDR data and pilot reports. During the event, the elevator was out of nose up elevator authority while A was engaged, however no trim
commands were output by A to pitch the airplane nose up. Four seconds after B was engaged (elevator remained where it was) the stab drove for about 6 seconds which relieved the elevator about 1 degree. There were other times in the data where A did command trim in both directions, so FCC A was capable of trim.

Boeing would recommend the following troubleshooting to verify the FCC stab trim interface as well as verification of the elevator position input to the channel A FCC:

Perform the DFCS Chapter 22 BITE Stab Trim rigging test, Elevator Rigging test (Both Single Authority and Dual Authority tests) and Mach Trim Rigging test. Verify that all the readings for these tests are within limits. As needed, Boeing will be available to support these checks by telecon. Please advise if the operator requests Boeing assistance by telephone during these checks and provide a contact time and number.

The noted condition could also be due to an incorrect FCC calculation of autopilot elevator authority upon which the trim thresholds are based. This calculation uses inputs from the ADCs. To help isolate this possible condition, we would recommend the operator swapping the left and right ADCs and IRUs.

## 7- BOEING REPLY, EXCESSIVE RATE OF DESCENT:

 12/6/2004 5:56:58 AM PST
## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to Ref /D/, Ref /C/ advised that Boeing had reviewed the provided FDR data and pilot reports. During the event, the elevator was out of nose up elevator authority while A was engaged, however no trim commands were output by A to pitch the airplane nose up. Four seconds after B was engaged (elevator remained where it was) the stab drove for about 6 seconds which relieved the elevator about 1 degree. There were other times in the data where A did command trim in both directions, so FCC A was capable of trim.

Boeing recommended the following troubleshooting to verify the FCC stab trim interface as well as verification of the elevator position input to the channel A FCC:

Perform the DFCS Chapter 22 BITE Stab Trim rigging test, Elevator Rigging test (Both Single Authority and Dual Authority tests) and Mach Trim Rigging test. Verify that all the readings for these tests are within limits. As needed, Boeing will be available to support these checks by telecon. Please advise if the operator requests Boeing assistance by telephone during these checks and provide a contact time and number.

The noted condition could also be due to an incorrect FCC calculation of autopilot elevator authority upon which the trim thresholds are based. This calculation uses inputs from the ADCs. To help isolate this possible condition, we would recommend the operator swapping the left and right ADCs and IRUs.

Ref /B/ provided results of the above recommended tests.
Ref /A/ advised that Boeing had reviewed the FCC BITE data provided in fax dated 3 December and the data indicates all test results passed and FCC operation appears normal. Therefore Boeing has no further recommendations at this time and recommends using both $A$ and $B$ channel autopilots. In the event the condition occurs again, please provide a listing of any DFCS in flight faults, FCC Bite test results for elevator and stab rigging checks and FDR data for review. The operator has reviewed the Ref /A/ and /C/ responses and is requesting clarification regarding the intermittent trim command output from FCC A. As reported above, the elevator was out of nose up elevator authority while A was engaged, however no trim commands were output by A to pitch the airplane nose up. It was also verified that there were other times in the data where A did command trim in both directions, so FCC A was (is) capable of trim.

The operator is requesting further Boeing recommendations and on-site tech assist.

## ACTION:

1. Based on the above data is replacement of the FCC A horizontal position sensor and sensor wiring check recommended?
2. Based on the above data, is an intermittent circuit between FCC A D1671B, pin 42, wire 102-20 to splice SP3677 a possible cause of the intermittent trim UP command?
3. Please advise any additional wiring checks to be performed.

8- BOEING REPLY, EXCESSIVE RATE OF DESCENT:
09-Nov-2004 03:42:22 PM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

The operator reports that, during descent with A/P A engages, VS mode selected and 1500 FPM selected on MCP panel airplane started a descent with a rate of 3000 FPM. Crew reported that this occurred two times. Crew reported that A/P operated normal.

Maintenance reported the following AFDS Bite results:
Possible Causes
Stab Trim M255
Elevator Pos. Sensor
Stab. Pos. Sen-1
Attached for review is DFDR data for the flight.

## ACTION:

The operator requests that Boeing review the submitted DFDR data and advise findings.
Reply,
Boeing has reviewed the FDR data and we do not identify any unusual autopilot operation noted in the reviewed data. The selected V/S is not recorded and therefore it is difficult to determine how well the autopilot is tracking vertical speed. We produced a derivative of the airplane altitude to determine where in the flight the vertical speed was 3000 feet per minute or greater. The resulting vertical speed data plot did not confirm any flight segment that exhibited a vertical speed of 3000 feet per minute or greater. As an added note, if the winds change with altitude, the airplane vertical speed will be upset in the short term from that selected.

## 9- BOEING REPLY, EXCESSIVE RATE OF DESCENT:

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

In response to Ref /D/, Ref /C/ advised that Boeing had reviewed the provided FDR data and pilot reports. During the event, the elevator was out of nose up elevator authority while A was engaged, however no trim commands were output by A to pitch the airplane nose up. Four seconds after B was engaged (elevator remained where it was) the stab drove for about 6 seconds which relieved the elevator about 1 degree. There were other times in the data where A did command trim in both directions, so FCC A was capable of trim.

Boeing recommended the following troubleshooting to verify the FCC stab trim interface as well as verification of the elevator position input to the channel A FCC:

Perform the DFCS Chapter 22 BITE Stab Trim rigging test, Elevator Rigging test (Both Single Authority and Dual Authority tests) and Mach Trim Rigging test. Verify that all the readings for these tests are within limits. As needed, Boeing will be available to support these checks by telecon. Please advise if the operator requests Boeing assistance by telephone during these checks and provide a contact time and number.

The noted condition could also be due to an incorrect FCC calculation of autopilot elevator authority upon which the trim thresholds are based. This calculation uses inputs from the ADCs. To help isolate this possible condition, we would recommend the operator swapping the left and right ADCs and IRUs.

Ref /B/ provided results of the above recommended tests.
Ref /A/ advised that Boeing had reviewed the FCC BITE data provided in fax dated 3 December and the data indicates all test results passed and FCC operation appears normal. Therefore Boeing has no further recommendations at this time and recommends using both $A$ and $B$ channel autopilots. In the event the condition occurs again, please provide a listing of any DFCS in flight faults, FCC Bite test results for elevator and stab rigging checks and FDR data for review. the operator has reviewed the Ref /A/ and /C/ responses and is requesting clarification regarding the intermittent trim command output from FCC A. As reported above, the elevator was out of nose up elevator authority while A was engaged, however no trim commands were output by A to pitch the airplane nose up. It was also verified that there were other times in the data where A did command trim in both directions, so FCC A was (is) capable of trim.

The operator is requesting further Boeing recommendations and on-site tech assist.

## ACTION:

1. Based on the above data is replacement of the FCC A horizontal position sensor and sensor wiring check recommended?
2. Based on the above data, is an intermittent circuit between FCC A D1671B, pin 42, wire 102-20 to splice SP3677 a possible cause of the intermittent trim UP command?
3. Please advise any additional wiring checks to be performed.

Reply:
The stab position data is used in determining trim thresholds. We also agree that an open between FCC A D1671B pin 42 would result in the A channel FCC being unable to command a trim up. Therefore, replacement of the stab position sensor and sensor wire verification is recommended.

We understand that the airplane has returned to service and we have no further recommendations at this time.

## 10- BOEING REPLY, EXCESSIVE RATE OF DESCENT: 12/13/2004 6:06:11 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

Refs /A/ thru /E/ discuss subject events and troubleshooting accomplished by the operator and Boeing recommendations.

Pilot reported the following: "During descent to FL160, A/P "A" engaged, FMA displayed ALT ACQUIRE but airplane continued descent." Airplane returned with A/P "B" engaged and no faults were noted. Airplane has been operating using A/P "B".

The operator has provided the attached DFDR data for the event. Please note the altitude reported above may be 1,600 feet vs FL160.

The airplane is currently out of service for troubleshooting.
ACTION:
The operator requests that Boeing review the attached DFDR data and advise findings.

## 11- BOEING REPLY, EXCESSIVE RATE OF DESCENT: <br> 13-Dec-2004 11:06:19 AM PST

## SUBJECT: AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT

## DESCRIPTION:

Refs /A/ thru /E/ discuss subject events and troubleshooting accomplished by the operator and Boeing recommendations.

Pilot reported the following: "During descent to FL160, A/P "A" engaged, FMA displayed ALT ACQUIRE but airplane continued descent." Airplane returned with A/P "B" engaged and no faults were noted. Airplane has been operating using A/P "B".

The operator has provided the attached DFDR data for the event. Please note the altitude reported above may be 1,600 feet vs FL160.

The airplane is currently out of service for troubleshooting.

## ACTION:

the operator requests that Boeing review the attached DFDR data and advise findings.
RESPONSE:
For this event, it appears that when ALT ACQUIRE was engaged the elevator moved about 1 degree to slow the rate of descent and then remained flat at that value for the 10 seconds it was in the mode. It appears there was not enough elevator authority on the A side to finish pitching the airplane up, and it continued to slowly pitch down until the autopilot was disconnected.

Also during the acquire, the autopilot was not trimming the stabilizer. Since the flaps were at 1, the autopilot trims based on elevator position. Therefore, the autopilot probably could not move the quadrant far enough. Based on this and the previous event, it would appear that the A actuator does not have the required authority, for whatever reason.

## II- CASE of AUTOPILOT OVERBANK

1- Case of Overbank Follow up:
Model: 737-500

## Pilot Report:

During Departure with LNAV engaged, when selecting $A / P$ " $B$ ", $A / P$ " $B$ " engaged then disengaged. After satisfying F/D again A/P selected then autopilot gives more than 35 deg. bank angle and increasing. A/P disconnected again followed by F/D Pitch bar out of view. F/D switches recycled off-on.

After Flap retraction and with aircraft was leveled A/P selected again operates normally ( A \& $B$ )

Maintenance Action:

- Autoflight system checked on ground from MCDU according to M.M. found operating normal.
- Last flight faults checked, found no faults recorded.
- Both IRS checked found OK
- Flight data recorder removed for read out and aircraft released for flight.
- Snag not repeated on the next flights but FDR read out for the subject flight shows that autopilot exceeds bank angle limitation.
- A/P "B" was deactivated and considered A/P "B" D. Defect according to MEL.
N.B

The airplane has a history in flight control problems, Boeing have the full details.
(Subject Flight FDR raw data available if needed)

Please do not reply. This message is the acknowledgement of your request.
Your Service Request has been received by The Boeing Company. Your request will be reviewed and a response provided in accordance with your request. Thank you for your inquiry.

## SUBJECT: Autopilot Overbank / DESCRIPTION:

T he flight crew reported the following:
During departure with LNAV engaged, AP "B" selected, the AP "B" engaged then disengaged. After satisfying F/D, again AP selected. At UTC 20:14 the autopilot gave more than 35 degree bank angle and increased. A/P disconnected followed by F/D pitch bar out of view, F/D switches recycled. Flap retraction and leveled, AP selected and operation normal.

Maintenance Action:
the operator maintenance checked on ground Autopilot system from MCDU and per MM no findings. Both IRS checked no finding. FDR removed for analysis and plane released back on flight line. Snag didn't reappear on the next flight. According to FDR the subject airplane had an autopilot exceeds bank angle limitations.
The operator deactivated the AP "B" and considered the AP "B" defected according to MEL.
The FDR raw data is available for Boeing review if required.
Action:
The airplane has a history of heavy flight control per Ref /A/ SR.
The subject Airplane is currently AOG for troubleshooting.
Please review the above information and advise the operator with any recommended troubleshooting.

3- BOEING COMPANY REPLY
28-Mar-2005 04:47:03 PM PST

REFERENCES:
Ref /A/ SR 1-57258797
SUBJECT: Autopilot Overbank /
DESCRIPTION:
The flight crew reported the following:
During departure with LNAV engaged, AP "B" selected, the AP "B" engaged then disengaged. After satisfying F/D, again AP selected. At UTC 20:14 the autopilot gave more than 35 degree bank angle and increased. A/P disconnected followed by F/D pitch bar out of view, F/D switches recycled. Flap retraction and leveled, AP selected and operation normal.

Maintenance Action:
the operator maintenance checked on ground Autopilot system from MCDU and per MM no findings. Both IRS checked no finding. FDR removed for analysis and plane released back on flight line. Snag didn't reappear on the next flight. According to FDR the subject airplane had an autopilot exceeds bank angle limitations.

The operator deactivated the AP "B" and considered the AP "B" defected according to MEL.
The FDR raw data is available for Boeing review if required.

## ACTION:

The airplane has a history of heavy flight control per Ref /A/ SR.
The subject Airplane is currently AOG for troubleshooting.
Please review the above information and advise the operator with any recommended troubleshooting.

As a follow-up, the operator attached the FDR data to Message Number: 1-1A4J4N.
RESPONSE:

We have analyzed the flight data recorder data provided by the operator, and are providing that analysis, followed by troubleshooting suggestions. The figures referred to in the analysis are provided as attachments to this response.

FDR Analysis

Analysis of the FDR data indicate that the overbank resulted when the pilot released the wheel, possibly to engage the autopilot, while the airplane had been trimmed with approximately 1.5 degrees of nose-left rudder pedal. Figure 1 presents the lateral and directional data for the event; for reference, the longitudinal parameters during the event are provided in Figure 2, although they did not play a significant role in the overbank.

The airplane performed a flaps 5 takeoff, becoming airborne at time 546 according to the air/ground logic. The airplane climbed out at 160 KCAS and shortly after lift off initiated a left turn from heading 295 towards heading 170. The wind was out of heading 050, increasing to about 25 knots in the air - this would constitute a quartering right tailwind transitioning to a quartering left tailwind. Note that FDR wind data are not valid on the ground.

At liftoff, the control wheel was deflected to about 25 degree right, and held at that deflection to maintain wings level. As the left turn was initiated, wheel was relaxed back to neutral and then deflected slightly left. At time 570 the wheel was relaxed to neutral and the A/P "B" was engaged - at this time the airplane had zero control wheel displacement but was rolling left at about 2.5 deg/sec. After about 1 sec , the A/P "B" disengaged. The control wheel was then deflected to the right, again to about 25 degrees, and arrested the roll at 30 degrees of left bank. At time 592 the control wheel returned to neutral and the A/P "B" channel was engaged again. As the wheel returned to neutral, the airplane again began to roll left at about 2 deg $/ \mathrm{sec}$. At time 597 the A/P " B " disengaged a second time and the CWS ROLL discrete (not shown) briefly engaged for 1 frame. Control wheel was deflected to 40 degrees right, the bank angle returned to zero and then continued right to about 4 degrees, then wheel was relaxed back to about 20 degrees right to hold bank angle between 5-8 degrees right.

During the entire event, from liftoff to the CWS engage and the roll back to 5-8 degrees right, the airplane appears to have been in a small nose-left sideslip. Rudder pedal indicates about 1.5 degrees nose left, and rudder position indicates about 2.7 degrees nose left. Furthermore, lateral acceleration persisted throughout the event at about -. 03 g 's, another indication of small sideslip angle. A simulation of the event confirms that, for the airspeed, altitude, and airplane configuration, a rudder pedal input of 1.5 degrees would give about 2.7 degrees of rudder and would require about 26 degrees of right wheel to balance. As the airspeed increased (FDR time 605 and on) the rudder blew down, and the amount of wheel required to balance reduced to about 20 degrees.

Figure 3 shows the takeoff roll. At time 505, the engines began to spool up - prior to this, the rudder pedal and rudder position parameters are both very close to zero (neutral). Shortly afterwards, several large pedal and rudder deflections occurred, accompanied by changes in heading. This is not unusual at the beginning of a takeoff roll and generally indicates that the pilot was aligning the aircraft on the runway centerline. By time 530 the rudder pedal deflections had subsided, but the rudder pedal position remained approximately at 1-2 degrees nose-left. The reason for this is unknown, but the deflection of pedal is confirmed by the accompanying rudder deflection of approximately 2-3 degrees nose left.

Figure 4 shows the FDR data after the event. At time 690, the flaps had been retracted to UP, and the airplane was just completing a left turn to heading 170, with bank angle returning to neutral. At this time, the pedal remained deflected at 1.3 degrees nose left, the rudder position was 2.2 degrees nose left, and 20 degrees of right wheel were required to hold the wings level. At this airspeed (now 205 KCAS) the simulation again indicates that this is consistent. As airspeed began increasing toward 250 KCAS, the rudder pedal and rudder position slowly neutralized; this was likely the result of manual trim adjustments by the crew, as the rudder appears to return in steps similar to the trim rate (note the expanded scale on rudder pedal on Figure 4). During the descent, as airspeed increased, the data indicate that the rudder pedal and rudder position remained
near neutral, further suggesting that the situation was corrected during the cruise.
Conclusion
----------

The FDR data indicate that PT561 experienced an overbank during an attempted autopilot engage because the airplane was in a small nose-left sideslip as the result of rudder pedal being deflected to approximately 1.5 degrees nose left. The reasons for this are unknown and cannot be determined from the FDR data, but the trim likely arose either from crew trim inputs during the takeoff roll (possibly inadvertent) or from something sticking in the rudder feel and centering unit. The simulation confirms that the sideslip resulting from the pedal input would have required approximately 25 degrees of right control wheel deflection to maintain wings level flight, as indicated by the FDR data. During each attempt to engage the " B " autopilot, the wheel was released to neutral and the airplane rolled at between 2 and $2.5 \mathrm{deg} / \mathrm{sec}$ as a result of the sideslipinduced roll.

Past experience with lateral trim issues on 737 's would indicate that flap rigging was not a factor, as the roll that can be produced by flap mis-rigging is not nearly large enough to require 25 degrees of control wheel. Small sideslip angles, on the other hand, can produce significant roll asymmetries.

From the data provided, the autopilot was working normally.
We suggest that the operator accomplish the following troubleshooting:

- Do a test of the rudder centering

AMM 27-21-00 Task S 735-012-001

- Do a test of the rudder pedal forces

AMM 27-21-00 Task S 735-014-001

- Do the rudder trim control system test

AMM Task 27-21-00-735-22-001
If any of the above tests are unsatisfactory, visually inspect the rudder feel and centering unit cam roller bearing to verify whether it is rolling on the cam when the rudder pedals are moved. If it is sliding on the cam instead of rolling, the bearing must be replaced.

4- Case of Overbank Follow up:
(Autopilot Overbank
29-03-05.
Dear Sir,
With refer to Boeing "MESSAGE NUMBER:1-1A7XEW", Required rudder tests in process. The operator notices that at 20:15:47, FDR data shows the follow:

Aircraft Roll 34.81
A/P "B" In Command
A/P Roll Mode LNAV
And with all previous condition autopilot still engaged till autopilot disconnected by the captain one second later.

Request:
Boeing Recommendation for the above situation.

5- BOEING COMPANY REPLY, 30-Mar-2005 02:01:38 PM PST

The operator has reviewed the FDR readout summary. The operator notes that FDR data point at time 20:15:47 reads:

```
Aircraft Roll 34.81
A/P "B" In Command
A/P Roll Mode LNAV
and with previous condition autopilot still engaged until disconnected by the
captain one second later.
```

The operator also notes that the autopilot usually limits roll to approximately 30 degrees while engaged. The operator requests additional explanation regarding the recorded roll angle of 34.81 with the A/P engaged and LNAV selected.

Action:

1) Please review the aforementioned query and provide an explanation.
2) Please advise if any additional troubleshooting is required other than that provided in Activity 1-1A7XEW.

## Reply:

Attached is an expanded plot of this event. The autopilot doesn't couple to the surface at the instant it is engaged. It first synchronizes the LVDT in the actuator to the surface position sensor in the quadrant. Also, FDR data is not sampled often enough to be sure of the exact timing; however it is probably the case that the detent solenoid that couples the autopilot to the surface was not actuated until the roll had already reached the maximum bank angle recorded. (The autopilot was engaged after the airplane had already established a roll rate to increase the bank angle to greater than 30 deg ). In addition, for this engagement, the initial data point for CMD occurred just prior to the control wheel reaching zero. Since the surface was moving at the time of engagement, synchronization to that surface would take somewhat longer than normal.

We do not have any additional troubleshooting recommendations regarding this event.

SUBJECT: Autopilot Overbank /
DESCRIPTION:
The following information has been received from the operator in response to Boeing request for flight fault information:
//QUOTE//As the aircraft return, the Captain on command recorded his report in the T.
Log Book, Autoflight was checked from FMC CDU using codes 100 and 300. No recorded faults found. Again after ur. email was received autoflight checked using codes 100 and 300 on 7th of April, 05 found one fault was recorded on flt -1 as follow * ERROR FCC-B* P2 P SPM TRIP B-8776 A/P DISC.

Nothing else was recorded.//UNQUOTE//

## ACTION:

Please review and advise if Boeing has any additional comments on the subject event or any additional troubleshooting/maintenance recommendations.

Reply:
The Bite fault note on 7 April is most likely not related to the event dated 19 March because the FCC will retain faults for only 9 flight legs.

The BITE message indicates the FCC recorded an internal fault. Also, the ERROR FCC-B indicates the fault was logged while the FCC was in the B channel and this computer was subsequently swapped to the A side when the BITE was interrogated.

### 2.6. Crew Behavior

Note:
All crew behavior subcommittee work has been included in the report with no differentiation between preliminary and otherwise.

The report reflexes the interpretation of the Egyptian Investigation Team and specialized advisors.

### 2.6.1 Flash Airlines Flight 604 Investigation <br> Crew Behavior Subcommittee

## Definition of spatial disorientation

Spatial disorientation is an incorrect perception of attitude, altitude or motion of one's own aircraft relative to the position of the Earth.

Type I spatial disorientation:
Unrecognized spatial disorientation. No conscious perception of SD.
Distractions are often antecedents to the accident. Crash with no distress or concern expressed.
No mayday or other than routine communications. Unusual or inappropriate aircraft attitude, but pilot does not make any appropriate corrective action. Pilot is apparently oblivious to the situation.

Type II recognized:
Conscious manifestation of a problem. Pilots often incorrectly refer to this experience as vertigo. Pilot recognizes conflict between perceived and intended or expected attitude. Can assume that the instruments are operating incorrectly. Might not properly react because of difficulty accepting indicated correct control input or might just be puzzled about the situation. Confusion might persist after recovery and lead to compounding of SD problem.
\{Veronneau, S.J.H. \& Evans, R.. (2004). Spatial disorientation mishap classification, data and investigation. Previc, F.H. \& Ercoline, W.R. (Eds) Spatial disorientation in aviation. American institute of Aeronautics and Astronautics.\}

## Conditions for establishing spatial disorientation

1. Presence of inaccurate or misleading vestibular cues.
2. Absence of visual cues or presence of misleading visual cues.
3. Presence of a distraction capable of drawing attention away from attitude displays.

## Examination of evidence pertaining to specific phases of the accident

1. From the roll input that initiated a right roll from wings level (from around time 104) through the statement by the Capt, "how turning right", (around time 02:44:37), the committee agrees that the above three conditions are met, and it is therefore possible that the Capt was experiencing type I Spatial Disorientation.
2. From the statement by the Capt, "How turning right", to the beginning of sustained left roll (around time 158), evidence for orientation or disorientation is inconclusive given currently available data.
3. After the first officer says "no autopilot commander" and sustained left control inputs begin the committee agrees that there is evidence that someone was properly oriented and manual recovery of the aircraft was initiated.
4. The committee agrees that there is no evidence suggesting spatial disorientation on the part of the first officer.
5. The committee agrees that the flight crew exhibited some positive CRM- related behaviors during the flight; however, further analysis in this area is required.
Closing Comments
This is a preliminary report. More work is needed to comprehensively address all human factors issues relevant to this accident, as needed.

### 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004:

According to the meeting held on Aug. $23-26,2004$ and attended by representatives from NTSB, BEA and Boeing. The committee agreed that the Captain was possibly experiencing "Type I Spatial Disorientation" in the 1st stage of the accident.

In the 2nd stage the evidence of "Spatial Disorientation Type l" is inconclusive.
In the 3rd stage there is no evidence of this disorder.
On 15 February, 2005 a message was received from NTSB including analysis of the Captain Behavior.

The scenarios included the word "Confusion "and not "Spatial disorientation type I".
Here is a comparative analysis of different labels of the Captains behavior.
Confusion:
By definition confusion means: a state of mild disturbance of consciousness where the person is perplexed and fails to distinguish properly different stimuli around him. It is caused by internal factor as illness; sever fatigue, drugs ... etc.

Differentiation from similar conditions can be shown in the following table:-

|  | Duration | Onset <br> \& Termination | Other crew members | Appropriate corrective action | Response to calls | Tone of speech | Reaction time | Insight | Anxiety | Astonishment | Rate of conversation | Orders |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Confusion | Long | Gradual | Not affected | Slow | Slow | Slurred | Prolonged | Partial | Probable | None | Few | Few |
| Spatial disorientation type I | Short | Sudden | May be affected | None | N. | N. | N. | None | None | None | N. | N. |
| Distraction | Short | Sudden | Usually affected | Yes | Can be normal | May be anxious | N. | N. | Yes | High | Few | Few |
| Mistake | Short | Sudden | Not affected | Yes | N. | N. | N. | None | None | None | N. | N. |

## Captain:

We apply the above table to the circumstances of the accident. The highest probability is that the captain suffered from distraction accuracy during the 1st stage only.

In favor of distracting:
The $1^{\text {st }}$ part of C.V.R. shows the talk and behavior of captain is completely normal.
The captain was the $1^{\text {st }}$ to attract attention of the rest of the crew that something wrong is happening in the airplane "see what the airplane did ".
This distraction could not be detected in the $2^{\text {nd }}$ or $3^{\text {rd }}$ stage.
This was shared by other crewmembers, as they assisted the captain in the same direction. Their observation and responses were centered on "right bank" and "autopilot".

Captain was alert with good concentration in the $2^{\text {nd }}$ and $3^{\text {rd }}$ stage as shown by his orders, responses and 3 appropriate actions taken (to the left):

- ${ }^{\text {st }}$ action Lt input after words "How Right"
- $2^{\text {nd }}$ action Lt input "OK come out"
- $3^{\text {rd }}$ action Lt input "OK come out"

During $1^{\text {st }}$ stage (critical stage) there was signs indicating astonishment (How Right) also signs of Hesitation (turning right sir).

## Crew members:

Include 3 persons Captain, 1st officer and extra crew 1.
Their behavior can be analyzed through two stages of C.V.R. record.

## 1 ${ }^{\text {st }}$ period (Pre-critical)

There were talks in between all crew members and between crew members and A.T.C. and attendant. Answers and comments are immediate and correct pointing to normal orientation and concentration. The mode and content of sentence show no evidence of disturbance of mood or intellectual functions. The conversations were calm and decisive with no evidence of anxiety or tension. There is no evidence of Euphoria or depressed mood.

## $2^{\text {nd }}$ period (Critical)

Starting by the phrase "Eddilo" (time 2:44:1) this was followed in few seconds by an important observation of the captain indicating that something is going wrong with the airplane.

This was followed by a l---- period of hesitation, astonishment lasting for less than ten seconds.

These manifestations were mostly evident with the captain. This period ended by the captain saying "how turning right ", then " OK come out ".

During this stage of hesitation the other crew members F.O. \& extra crew 1 their comments and answers were correct but the responses are anxious and rapid.
All crewmembers are anxious during this period of hesitation and astonishment ended by the captain saying "how turning right ".

All these problems were corrected to normal in the remaining period (after OK come out) according to the table of differentiation these are manifestation of distraction.
Both F.O. and extra crew 1 did not contradict the captain's orders or actions until the end of accident. This shows that in their estimation the captain was acting in the proper way.

If they felt he is wrong they would have (at least) suggest any other action.
As the crew were in stress this logically abolishes the respect of seniority.
If captain is acting wrongly they would have screamed loudly and aggressively there is no evidence of this (C.V.R.).
The extra crew 1 is an experienced pilot - Age 42 - ( 4000 h . flight)

2.6.3 Flash air CBS Sub-group comments (25 August 2005)

# Flash Air CBS Sub-group Working Document 

24 August 2005

## Initial Factors for which we have evidence

Factors Conducive to a Fatigued State - Time of day, cumulative work hours, 2(3) early morning departures

Factors Conducive to the Occurrence of Spatial Disorientation- Dark night,, previous Russian ADI experience, low time in type,

Factors Conducive to a Authority Gradient Between Captain and Copilot: (a) large differences in aviation experience (Captain 7000 hours, copilot 800 hrs ), (b) percieved differences in social status/rank (Captain retired Air Vice Marshal with prior military career, Copilot just beginning his career in aviation with no prior distinction), (c) large differences in age (53 years / 25 years)

The following facts exist

- No training in spatial disorientation, upset recovery, automation, or CRM training provided by Flash Airlines (not required by civil aviation)
- Captain and Copilot low time in type (automation, handling)

## Pre takeoff events

Checklist execution and handling of interruptionsgenerally good
**Captain's questions regarding Cairo ceiling info provided by ATC - CRM issue because he never resolves the F/O and observer uncertainty on this issue

Discussion between Capt. and engineer regarding unknown aircraft discrepancy - Not enough information to evaluate crew handling of this issue

Takeoff briefing "Standard briefing." Airmanship and CRM issue - lack of professionalism and it is the first departure of day

## Pre takeoff events

[Before takeoff Checklist- item change for CVR, he did say "Before takeoff check...."-transcript]

2:41:34 - Captain's request that F/O verify departure altitude FO not repeating question to ATC initiallypossible fatigue and workload factor in not hearing captain's request to check altitude CRM - issue because of F/O's responses.

Captain's request that F/O verify departure altitude Fatigue or confirmation issue- Captain should have heard altitude during initial clearance from ATC. Also, altitude was already set in MCP heading.

## Departure events

**Captain is possibly not using boom mike - professionalism/CRM or possible unintentional error unchallenged by F/O.

Captain's first heading select call occurred below 10 feet AGL, Error in sequence as he called it early. Possible fatigue issue. TOGA display inoperative proceedure called for heading select at 400 feet.

## Departure events

- Failure to track pitch and airspeed deviations (22 degrees up and -30 knots speed error/eventually 35 knots) - indicators of distraction and possible fatigue. Failure to track FD for 15 seconds prior to autopilot call ( 25 seconds total), indicative of distraction (attention directed elsewhere), SD in pitch axis (following vestibular cues) - other items or inattention (from attempt to engage autopilot for last 10 seconds) or slow response
- Attempted autopilot engagement, disengagement, and subsequent mode changes- created a period of distraction. CRM issues - communications unclear during event, inadequate post event clarification; FO issued duties of after takeoff checklist and this item- after takeoff checklist completed not heard - could be reason for FO actions during this time

## After takeoff issues

- Beginning of right bank- (at time of heading select statement)--- Lack of a quick correction indicates distraction from the attitude indicator, vestibular perceptions are inaccurate, captain does not realize airplane is entering a right bank, and the result is spatial disorientation for the captain. Distraction could result from any of the following causes: Fixation on a particular display or display element, following a shortest-distance flight director command (from undocumented MCP heading selection), lack of attention to roll and pitch with corresponding trim effects, or reflection on problems that may have occurred or the previous autopilot sequence or unexpected aircraft response or focusing on something else. CRM issue - FO not issuing timely notification of undesired bank - fatigue, distraction, authority gradient [Note: look at possibility of "step function" leans.]
- Captain's statement "See what the aircraft did" and lack of verbal response from F/O - CRM, fatigue issues. Captain has never clearly communicated what is going on since the time of his exclamation during the attempted autopilot engagement sequence. Continued right bank indicates he is still distracted from airplane control.

## After takeoff issues

- Lack of communications of the crew during right turn -CRM -regarding unintentional right turn or unsuccessful attempt to maintain wings level at 140 heading -22 seconds- fatigue (inattention/distraction)
- "Turning right sir" exchange- Indicates Captain is spatially disorientated and F/O is not. Captain's reaction accompanying reply, "Ah" is to increase roll to the right for first 4 seconds - indicates SD, possible fatigue,, fixation on inappropriate element of attitude display (e.g., roll pointer) / perceptual reversal.
- "How turning right" exchange- attempt to get an explanation from self or FO. Indicates SD is being recognized and is transitioning to type 2 SD, captain attempting to resolve conflict between his internal perception of attitude and the attitude shown on the EADI (Took 18 to 20 seconds for resolution in one previously documented accident, or 27 to 33 seconds to resolve and stabilize airplane from climbing right attitude in Air Force study). No FO statement indicates inadequate CRM.

## Departure events

"Ok, come out"- expression of necessity of action / statement of desired outcome. During an area of generally sustained inputs in the wrong direction there is aileron movement for a period of 3 seconds in the correct direction of movement with movement past neutral for 1 second.

Overbank callout by FO- Indicates CRM issues - late callout, (not directive).
Capt response to first overbank callout - no direct response and may not have been need based on his previous words

Wheel oscillations for the next 13 seconds, predominantly to right - oscillating wheel motions predominantly in inappropriate direction resulting in increased right bank.
"Autopilot" (Capt) - Suggests captain is looking for a solution to correct the overbank problem and/or spatial disorientation (bailout mechanism). Similar to previous statement autopilot engage, differs from previous comments describing problems ("edillo", "see what the ...") Command is inappropriate because the AP is not intended to recover from unusual attitudes. (Ref FCTM 1.30).
"Autopilot in command" (FO) - automatic response (when FO pushes AP button) following captain's order

## Departure events

"tsk, tsk" sound - vocalization by FO expressing disapproval or uncomfortable with situation.
"Overbank, Overbank, Overbank" by FO. F/O continues to provide same observational callout, and does not escalate his assertiveness by asking questions, providing suggestions, issuing commands, or taking control of the airplane. Indicates possible problems with inexperience, authority gradient
"No autopilot commander" - First officer is observing and communicating that autopilot is not connected.

Retard power calls from observer - comment very late in sequence. Observer did not comment on unsafe condition developing in the flight deck until very late in the sequence

Recovery effort - appropriate roll and power inputs, but pitch inputs were insufficient to recover within remaining altitude.
2.6.4 Major factors contributing to Spatial Disorientation (Contribution by BEA)

## Major factors contributing to Spatial Disorientation

- Flight environment
- Night flying
- Absence of clear references (lack of clear horizon, ground/sky confusion...)
- Erroneous false horizons (shoreline, sloping cloud bank...)
- Isolated light sources
- IFR flights
- Transfer from external visual to instruments cues
- Flight over featureless terrain
- False perception of height

## - Aircraft Factors

- Inadequate or inoperative instruments
- Visibility of instruments

## Major factors contributing to Spatial Disorientation

- Flight maneuvres
- Prolonged angular motion
- sustained motion not sensed
- somatogyral illusions on recovery
- no sensation of bank during coordinated turn
- cross-coupled and "g-excess" illusions if head movement is made while turning
- Subthreshold changes in attitude
- "the leans" induced on recovery
- Air crew Factors
- Training, flight experience, and proficiency in instrument flight
- Physical and mental health
- Alcohol and drugs
- Workload and capacity
- Fatigue
- Circadian disrhhythmia (jet lag)
- Additional communications or tasks

## ESTIMATED PILOT PERCEIVED POSITION

Merfeld, "Observer Theory Model", 2001

- Source:
- FDR data
- Limitations:
- No visual orientation data, no audio, proprioceptive inputs
- Individual differences - especially threshold
- Possible head movements not taken into account
- Results:
- Estimated pilot perceived position

## Roll, Roll rate and aileron movements

$>$ Possible sub-threshold roll input
$\Rightarrow$ Inducing "the leans" at the end of the turn
$>$ Prolonged angular motion
$\Rightarrow$ Approximately 50 seconds of slow roll rate to the right
$\Rightarrow$ Large aileron input to the right at the end of the slow roll rate BEA

## Roll, YZ GIF angle, Perceived Roll

$>$ Low sensation of the sustained and prolonged roll rate to the right $>$ Low sensation of bank during turn to the right
$\Rightarrow$ Confirmation of Mc GRATH results

## Pitch, XZ GIF angle, Perceived Pitch

2.6.5 Fatigue study in collaboration (Contribution by BEA)

## LAA :

## Laboratory of Applied Anthropologie

 part of medicine university PARIS V
## Activity : ergonomics

-Biomecanics,
-Psychophysiology,
-chronobiology

Numerous works in aviation for the DGAC and the BEA
BEA

## Data and limitations

- Flight periods extracted from the factual report
- Period 1 month
- Repositionning flights : unknown
- activity between the flights : unknown

## The Avoidance of Excessive Fatigue in Aircrew

Arab Republic of Egypt ECAR Part 121
Ministry of Civil Aviation
-Maximum cumulative duty hours : the average weekly total of duty hours shall not exceed 50 hours, averaged over any 4 consecutive weeks. All types of duty, flying duty, ground duty, split duty, standby and positioning shall be counted in full for this purpose
-We don't have the information (repositioning, standby...)
-Maximum monthly flying hours: the maximum number of flying hours which a cockpit crew member may be permitted to undertake during any 30 consecutive days shall be 100.
-According to the factual documents : nearly 80 flight hours
discrepancies between the data collected in the factual report and the FDR data
we're unable to conclude about these points of the regulation

## Arab Republic of Egypt ECAR Part 121

Ministry of Civil Aviation

## Crewmembers shall :

- Not work more than seven consecutive days between days off;
- 20/12 to 27/12 : 8 days without days off,
- Have 2 consecutive days off in any consecutive 14 days;
- $18 / 12$ to $3 / 01$ : $\mathbf{1 6}$ days without $\mathbf{2}$ consecutive days off.

## Results : cpt

## Duty time (last month) :

- At least 140 duty periods hours
- At least 80 flight hours
- Period of 8 consecutive days on duty (legislation 7)
- Period of 16 consecutive days on duty, with only 1 day off (legislation 14)

Arab Republic of Egypt ECAR Part 121
Ministry of Civil Aviation

- The ECAA will conduct periodic and spot checks of operator's records and pilot in command reports to assess whether the operator's planning of flight schedules and duty in general is producing results which are compatible with the limitations provided for in the operator's scheme.
- Available report?

## Results

- No evidence of circadian disrythmia (jet lag),
- Heavy workload for the captain
- Sleep deficit due to
- workload,
- Planning (2 early take-off in 2 days, copi 3)
- Influence of the new year celebration (ldg 2300 the 31 december), repositioning flights ?

## Crew performance and fatigue

Sleep and alertness<br>Recommendations guide 1998

## Results : fatigue

- Physiological
- Reduces
- Muscular strengh
- Binocular vision
- Muscular coordination
- Increases
- Visual accomodation delay
- Psychological
- Reduces
- Memory
- Ability to communicate and cooperate
- vigilance
- Increase
- Irritability, anxiety
- Lapses, Errors
- Response time..

## Conclusion:

important to take into account the influence of the fatigue (contributive factor) in the crew behaviour (interference with spatial desorientation, CRM...)
need to know the exact planning to amend the LAA study

# Flash Air Flight 604 Perceptual Study 

B737
NIGHT TAKE-OFF

# Preliminary Findings 20 AUG 2004 

Braden J. McGrath, PhD.

Aircraft data from the flight data recorder (FDR) that influences spatial orientation is currently being analyzed and evaluated at NAMRL at the request of William J. Bramble, Jr., Ph.D., Senior Human Performance Investigator, National Transportation Safety Board, Office of Aviation Safety, Human Performance Division.

## Background

Spatial disorientation (SD) and subsequent loss of situation awareness (LSA) mishaps for military air forces, commercial aviation, and general aviation have an estimated annual cost in the billions of dollars. From 1999 to 2002, the US Navy experienced 36 mishaps where SD was a major causal factor. The Naval Aerospace Medical Research Laboratory (NAMRL) has developed an SD mishap analysis tool to support US Navy mishap boards in their investigations, to provide insight into the problem of SD in naval aviation, and to train aviators to avoid SD mishaps. The SD mishap analysis tool uses spatial orientation models and computer animation techniques to produce threedimensional (3-D) computer simulations of SD mishaps.

NAMRL provides no-cost assistance to other government agencies as it allows NAMRL researchers to make improvements to the SD mishap analysis tool by gaining access to different types of mishap profiles and data not often available in Navy mishaps. In particular, NAMRL is assisting the NTSB for the Flash Air Flight 604 mishap as it allows NAMRL researchers to investigate a mishap that has low rotation rates in a 1 G environment, and access to FDR data not often available in Navy mishaps.

## Method

Step 1: Using data from the flight data recorder, estimates of the 3-D angular position and velocity, and 3-D linear acceleration experienced by the pilot of the mishap aircraft are calculated using the mathematical analysis software package, MatLab ${ }^{\text {TM }}$ (The MathWorks, Inc.) in a format required for the SD analysis

Step 2: The estimates of the 3-D angular position, angular velocity, and linear acceleration of the mishap aircraft are input into two spatial orientation models to produce an estimate of perceived pilot orientation. The SD mishap analysis tool uses both an observer theory model (Merfeld, 2001), and a classical systems model (Grissett, 1993) to estimate spatial orientation perception using the modelling analysis software package Simulink ${ }^{\text {TM }}$ (The MathWorks, Inc.). Both of these spatial orientation models do not include visual or somatosensory inputs, and are based on vestibular models from current literature and additional data from centrifuge, aircraft experiments, and aircraft mishaps gathered at NAMRL over the previous 40 years. The spatial orientation models assume that the pilot is not using outside visual horizon cues, and the pilot does not look at the aircraft instruments.

Step 3: To determine the accuracy and validity of the perceived pilot orientation, including analyses when the model results are significantly different, the perception results can be evaluated using data from other sources, including pilot control inputs, expert advice on the mission, cockpit voice recorder and eyewitness accounts. If required, the estimated perceptual results are modified to overcome the limitations of the spatial orientation models to produce a more accurate estimation of the perceived pilot orientation.

## Results

Step 1 is incomplete as the data analysis assumes pilot is situated at the FDR sensor location. If requested, NAMRL will recalculate the data using accurate pilot - sensor position data. For Step 2, both the NAMRL model (Grissett, 1993) and the Merfeld model (Merfeld, 2001) analyses are complete.

1) There is a difference between the resultant gravito-inertial vector angle and the aircraft attitude in pitch and roll. Due to this difference, both perceptual models estimate pitch and roll misperception. not been validated by additional analysis using the Merfeld or other perceptual models .

2) The angular rates are in the range of $1.0-2.0 \mathrm{deg} / \mathrm{sec}$. This magnitude is within the range of thresholds for detection of angular motion published in the literature. This indicates possible undetected attitude changes - especially the roll because of the resultant YZ GIF angle remains at zero. In addition to the Merfeld model, NAMRL researchers will attempt to investigate this possible sub-threshold roll input more thoroughly using additional models published in the literature.

## Flash Airlines 737 SU-ZCF Thread Diagram

 Step 1 - Identify Chronology of Events

This and following slides illustrate
the process used to create the
thread diagram.

### 5.0 Roll back towards wings level

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| WIdening Departure Pattern p3-GD34 (Intentional control action) | Crief pliot reporta some crews choose to wilden their departure patsern by scuaring tum at approximately $90^{\circ}$ to runway heading. The wings level heading. 142", is $80^{\circ}$ from the runway hesding. It has to be noticed that the crew never briefed the departure as it is usually done (headings, sets, daplays,...). Al the clalogues between the Capt and the FO before the turn is about " 140 ". This match with what sald Flash ex-Chief plot in his last atatement about widening pattern. <br> The alrcraft remained near heading 140 for 9 seconds. Roll rate decreases as aircrat: nears 140. <br> The observer was also a friend of the airine director of operations riding as a passenger. The PF (captain) may have warted to ensure that he did not violate the local VOR althute crosaing practice in the presence of the director's friend. <br> The previous day's departure from ash included a 270 turn to right and the filight crossed the VOR below 7000 ft . The approach chart In the AIP states minimum quadrant altude is $10,100 \mathrm{f}$ NW of VOR. | The anme crew made a similar departure about 24 hours previously, at a heavier weight without widening their departure. <br> There is no dacusaion about this maneuver recorded on the CVR. <br> There is no evidence on FDR that flaht drector was used for this maneuver. |
| Mistaken understanding of "Initially $140^{\circ}$ p3 - G035 (Intent.) | ATC ciearance: "Destination Caro as fied, cilmb initilly fight ievel one four zero" FO read back "deatination Calo via flight plan route one four zero". Captain later asks for contimation about "Initially $140^{\prime}$ from FO and for FO so confrme whth ATC. After inltal clearance, nelther ATC nor FO specity whether "140" refers to a hesaing or aptude. Alrpiane rols wings level on exactly 140. | No request from captain to set seiected heading to 140. <br>  <br> "initlaly" phrase refers to altitude, not heading. <br> "14000" set in artude window immediately after ATC ciearance and was in the window during subsequent discussion and confrmation whith ATC. |
| To level wings prior to engaging autopliot p3 - G036 (intent.) | On FDR fight 10, the crew did not engage the AP untl wings level at approxmately 9000 ft following completion of a series of tums affer takeott. | On FDR fight 9 , the crew engaged the autopliot in the middie of a $270^{\prime}$ tarn at a bark angle of 20 to $25^{\circ}$. |
| Plot loses awareness of heacing or bank p3 - G039 (unintent.) | Roll out coincident with passing over coastine and resulting loss of outalde visual references. Prich begins to devisted from expected value. Malesding vestbuar cues were present: | Athuse information avsiable on displays to 3 fight deck occupants. |

### 7.0 AP Engagement

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| PF requests $A P$ PF cancels request PNF pushes CMD button anyway | Consistent wh company practice. <br> Impresslon from CVR is that the first offcer is manipulating the MCP Controls prior to AP engagement. <br> CMD bution is located on night slde of MCP, closer to F/O. | Boeing procedure is for PF to push the CMD button. |
| PF requests AP PF prompts PNF due slow response <br> PNF pushes CMD button | Consistent with company practice. Impression from CVR is that the first offcer is manlpulating the MCP Controls prior to AP engagement. CMD bution is located on night slde of MCP, closer to F/O. | Boeing procedure is for PF to push the CMD button. |
| PF pushes CMD button, gets no response. PF questions no response and makes second push. PNF reports AP engaged. | Boeing procedure is for PF to push the CMD bution. | According to Flash chlet plot, procedure was for PF to request AP and PNF to push the button. The Flash chlef pliot acknowledged thls was opposite to Boelng recommended procedure on thils point. A written procedure could not be found in the avallable Flash Operations Manual (some pages were missing). |

### 9.0 Aileron Motion (Right Roll) <br> (Need to revisit)

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| Manual plot Input p2 - G029 | Magnitude and duration of alleron motion recorded on FDR data were compared to simulated autopllot behavior if engaged and to two previous manual control motions recorded in previous 30 seconos. The motion recorded of the FDR is more simliar to the previous manual Inputs than to the simulated autoplot behavior. <br> (The simulated autoplot behavior presumed normal autopllot behavior. The recorded motons are within the autoplot authority IImits.) <br> (there was no consensus on this point) | Amplitude and direction of alleron motion recorded on previous FDR data showed some simliartiles with a/p behavior. <br> (there was no consensus on this point) |
| AP Input due force sensor tallure p3-G030.1 |  | The force sensor was known to be working properly at AP engagement, about 1.5 seconds earller. Motion of aleron was nelther abrupt and nor in one direction only. as would be expected from a force sensor fault. |

### 10.0 Autopilot Disengagement

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| A/P disengages due to manual disconnect p2 - G029 | Warning length is consistent with "double clicx" typical of manual disconnects (within allowable warning duration tolerance). | No disengagement callout by crew on CVR. |
| AP disengages due to Interiock faut! p1 - G001.1.1 |  | Requires interlock fault in the 3 seconds since the AP successfully engaged. |

### 11.0 Right Bank Begins (<20 bank)

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| Capt Ioses sltuational awareness with correct PFD Indications present (e.g. distraction, misinterpretation, etc) p3-G039 | Refer to CSS report. | Captain just asked for heading select and therefore was Ikely looking at PFD at that time. |
| Capt loses S.A. while following erroneous EADI oftset reference p3-G037 |  | Fault display on EADI unusual enough to be evident to crew and unllkely to be milstaken for valld data <br> Captain's control inputs more closely match response to percelved valld input. <br> We know the EADI was OK. Even if it falls (It would have black screen). Stand by Horizon was supposedly functioning. We have no comment from the Capt nor from the FO nor the Observer about fallures on this instrument. |
| Capt loses S.A. whlle following FD commands due to erroneous selected heading (p5 - GD47) or unintended turn direction (p6 - G051, G049.1) | The captain just asked for the filght director by calling for "Heading Select" FDR data shows heading select mode engages. The pitch FD error is decreasing during this time, therefore the pllot was likely following the filight director in both pitch and roll. <br> Accident alrplane had "shortest direction" turn behavior on FD for turns $>180$ degrees. Simulator used for training at RAM did not behave this way - it always honored direction of turn on MCP knob. | Capt asked for Heading select. <br> FDR data for selected heading (recorded at 64 second intervals) Indicate the FD would have been commanding a left, not a right, tum. |

### 13.0 Overbank (1 of 2)

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| Capt expertences spatial disorientation (Type II) | Reter to cas report |  |
| Capt misinterprets ADI indlcations | Reter to Cas report |  |
| Following erroneous EADI - offset alrplane reference p7 - GD94 |  | This faut may have served to confuse the captaln, but two other sources of attitude information would be avallabie. The fault would not ikely have led to a drastic charge in the pllot inguts, as is evidenced by the change from <1"/sec to $>3^{\circ} / \mathrm{sec}$ roll when the FO announces "turning right". |
| Plot input in the presence of autoplot actuator hardover due to intermiltent triple fault 5 <br> p11-G055, G056, G057) | Reter to Cas report reparding CVR comments. | Requires multiple faults to occur simultaneously. <br> Fallures could anect the arcratt trajectory. Demonatrased in the M-Cab that all the faults except the quintupie fault (1.e. 80 los on the wheel) were easly recoverable. |

### 13.0 Overbank (2 of 2)

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| Plot input in the presence of aleron trim runaway <br> a) Full p20-G043 <br> b) Partial p20-G044 | Refer to cas report reasraling CVR comments. | Requlres two faults to occur almutaneously (one of which may be latent) or manusi activation. <br> Trim could atect the arcrat tralectory uniess addional wheel forces are appled to counter the trim. Demonatrated in the M-Cab to be easily recoverable. |
| Scenario 10 (Spoller wing cable (am) in at tme 92450 and clears at 92472 | MCA requesta simuation be rejone at point on maximum whee deflection. | MCA requests almulation be redone at point on maximum wheel defection. <br> Recorded wheel defection reguires maximum of $\sim 00$ lbe witch may resus: In an audible chsnge in valce. Recorded alieron position incics:es wheel was moved smocthly trough the point of 60 los torce incresse on multipe occasion. Volce effects and amoomness of control requre turther study. |
| Scenario 10a (F1O wheel Jam) In at time 92450 and clears at 92472 | MCA requests simuation be redone at point on maximum wheel defection. | MCA requests almulation be redone at poirt on maximum wheel defection. <br> Recorded wheel defection requires maximum of $\sim 60$ lbs with may resus In an audible change in voice. ### 15.0 Recovery Attempt

| Scenario | Pros | Cons |
| :---: | :---: | :---: |
| $\begin{aligned} & \text { Capt Input Only } \\ & \text { p1 - G009 } \end{aligned}$ | Captain was the pilot flying with nothing on CVR to suggest that control was transterred. | Refer to CBS report regarding CVR comments. |
| FO Input Only p1-G011 | Refer to CBS report regarding CVR comments. | FO does not announce he is taking control. |
| Joint Attempt | Previous upset events have resulted in multiple crew making control inputs. | FO does not announce he is taking control. |

The study performed by a team of qualified Human Performance Specialists have come up with findings summarized as follows:

- An event starting from the time of call for autopilot engagement through the time of the captain statement "see what the aircraft did" caused obvious crew distraction. This distraction may have developed to Spatial Disorientation (SD) to the captain until the time the F/O announced "A/C turning right " and acknowledged by the captain.
- There are conflicting signals in the following period of time ( $\sim 17$ seconds), it is unclear whether the captain remained in SD or was the crew unable to perceive the cause that was creating an upset condition until the time when the F/O announced that there was no A/P in action.

After the time when the F/O announced "no A/P commander" the crew behavior suggests that recovery attempts were consistent with expected crew reaction, evidences show that the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

## 3 Conclusion

## SUMMARY

General background:
The A/C was serviceable at take off and was operated within the approved limitations.

The crew members held appropriate licenses and were qualified for this flight.
There was no indications of specific concerns about the flight or any tension between the crew members

## 1. Airplane Performance Evaluation: ${ }^{1}$

Note:
The evaluation is based on factual information (FDR data and CVR recorded information) and the data gathered during the investigation

### 1.1 Simulation procedure

Based on the FDR data, a kinematic consistency (KINCON) process was used to supplement the FDR data and calculate additional parameters to be used in the performance analysis. Additional simulation was conducted using the Boeing MCab facility.

Analysis of the simulation results showed the following:

- The motion of the control surfaces showed consistency with the recorded motion of the control inputs, with the exception of control wheel (because of the unreliable recorded parameter)
- The results obtained from the M-Cab tests indicate that the computed parameters are quite sensitive to the values of the used input parameters.

### 1.2 Weight and Balance

Although the average weight for passenger used in Load and Trim sheet for the Weight and Balance calculation was not the one given in the airline Flight Operations Manual, none of the available data relevant to the airplane weight and balance showed evidences of airplane loading abnormality. Computations of the airplane weight, c.g. location, stabilizer setting and the Take Off speeds V1, VR, V2 were correct.

[^47]1.3 Analysis of radar data

An examination of the radar data and the FDR data showed that the path of the accident airplane as derived from the radar data is consistent with the path as derived from the FDR date

## 2. Analysis

### 2.1 Airplane systems behavior ${ }^{2}$

No failure or abnormal behavior was found in the following systems:

- Environmental Control System (ECS)
- Fire Fuel system
- Landing Gears
- Engines
- APU.

Thus, a possible contribution of these systems to the accident could be ruled out. Within the technical area, only "Flight Controls" and "Auto Flight" could have contributed to the accident

### 2.2 Crew behavior ${ }^{3}$

Evidence of distraction possibly becoming spatial disorientation is observed from the time of start of right turn until the announcement of aircraft turning right, after which it is unclear whether the captain recovered or remained in the state of spatial disorientation. After the call "No autopilot commander", the crew behavior appears normal.

[^48]
## 3. Analysis of the chronological main events: ${ }^{4}$

Based on the facts collected about the flight, as well as the aircraft and the flight crew, a fault tree was established and examined in details, which lead to the ruling out of a number of possible conditions for the accident. Only a few of such conditions could not be ruled out and are reflected hereafter (organized according to the fault tree structure)
3.5 Roll back towards wing level ${ }^{5}$

The following conditions could not be ruled out:

- Pilot widening departure pattern (intentional control action)
- To level wings prior to engaging autopilot (intentionally)
- Pilot loses awareness of heading or bank (unintentional)
- Anomalies with the lateral control system

The investigation could not determine a higher possibility to any of the above findings based on the given data.

[^49]
### 3.7 Autopilot engage sequence

The following conditions could not be ruled out:

- Captain requests autopilot, F/O pushes CMD button anyway
- Captain requests autopilot, Captain prompts F/O due slow response, F/O pushes CMD button
- Captain pushes CMD button, gets no response. PF questions no response and makes second push. F/O reports autopilot engaged.

The investigation could not determine a higher possibility to any of the above findings based on the given data.
3.8 Mode change from HDG SEL to CWS-R

The following conditions could not be ruled out:

- Autopilot Engagement with FD Roll Bar > 7 Degrees (with time lag) (no failure condition)
3.9 Aileron move in direction of right roll
- Pilot input
- Lateral system fault:

The investigation could not determine a higher possibility to any of the above findings based on the given data.
3.10 Autopilot Disengagement indications on the FDR and CVR

The following conditions could not been ruled out:

- Automatic Disconnect Interlock invalid
- Manual Disconnect

The investigation could not determine a higher possibility to any of the above conditions based on the given data.
3.11 Airplane begins roll to right

G- Lateral control system:
G.1. Pilot input:

## G.1.1 Following FD, FD Commands Erroneous, Erroneous Selected Heading Data

G. 2 Autopilot Initiated

## G.2.2 Uncommanded (actuator faults only)

G.3- Lateral System Fault
G.3.6 Trim/Feel Unit Fault
3.13 Right roll continues to overbank with ailerons activities

The following conditions could not be ruled out

1. NA
2. Lateral Control System
2.1 Conditions related to pilot input: (See section2.6)
2.1.1 Following Erroneous EADI, Alternate Instruments Not
Cross-Checked
2.1.2 Loss of Situational Awareness, Captain experiences SD Type II
2.1.3 Loss of Situational Awareness, Captain misinterprets ADI indications
2.2 Conditions related to Autopilot:
2.2.1 Autopilot Actuator Hardover Fault
2.3 Conditions related to Lateral System Faults:
2.3.1 Trim/ Feel Unit Fault.
2.3.2 Temporarily, Spoiler wing cable jam (Spoiler offset of the neutral position)
2.3.3 Temporarily, F/O wheel jam (spoilers offset of the neutral position)

The investigation could not determine a higher possibility to any of the above conditions based on the given data.
3.14 Flight crew CVR autopilot announcements

1. Requests for Autopilot Engagement
2. Announcement of Autopilot Status (Announcement of "Autopilot in Command" made by the F/O):
3. Announcement of "No autopilot commander" made by the F/O:
4. Announcement of Perceived Autopilot Behavior
5. Requests for Autopilot Disengagement

The investigation could not determine a higher possibility to any of the above conditions based on the given data.
3.15 Rapid left roll towards wings level

1- Capt. Upset Recovery Attempt
2- First Officer Upset Recovery Attempt
3- Joint Upset Recovery Attempt
From the above, Captain Upset Recovery Attempt seems a higher possibility
3.16 Impact with water

Although an attempt to correctly recover was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

## FINDINGS

3.1 Possible causes :

- Trim/ Feel Unit Fault (Aileron Trim Runaway)
- Temporarily, Spoiler wing cable jam (Spoiler offset of the neutral position)
- Temporarily, F/O wheel jam (spoilers offset of the neutral position)
- Autopilot Actuator Hardover Fault
3.2 Possible contributing factors :
- A distraction developing to Spatial Disorientation (SD) until the time the F/O announced "A/C turning right"with acknowledgement of the captain.
- Technical Log copies were kept on board with no copy left at departure station.
- Operator write up of defects was not accurately performed and resulting in unclear knowledge of actual technical status
- There are conflicting signals which make unclear whether the captain remained in SD or was the crew unable to perceive the cause that was creating an upset condition until the time when the F/O announced that there was no A/P in action.
- After the time when the F/O announced "no A/P commander" the crew behavior suggests the recovery attempt was consistent with expected crew reaction, evidences show that the corrective action was initiated in full, however the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.
3.3. Additional findings:
- The ECAA authorization for RAM B737 simulator was issued at a date later than the date of training for the accident crew although the inspection and acceptance test were carried out at an earlier date.
- Several recorded FDR parameters were unreliable and could not be used for the investigation.

## CONCLUSION

No conclusive evidence could be found from the findings gathered through this investigation to determine a probable cause. However, based on the work done, it could be concluded that any combination of these findings could have caused or contributed to the accident.

Although the crew at the last stage of this accident attempted to correctly recover, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

## 4. Recommendations:

## Manufacturers- Operators:

1. Joint effort should be made to minimize MEL-CDL-DDL allowances to avoid lowering safety standards by overloading pilots, and ensure that whenever found necessary to maintain such items, very clear procedures addressing pilots and maintenance crews to be made available
2. Efforts should be made to enhance the function and reliability of FDR and CVR due to the importance of the data obtained to the safety of the aviation industry
3. Clear engagement status indication for the autopilot should be made available to the crew to avoid any possibility of incorrect perception or ambiguity.
4. Based on data collected from different operators using this autopilot and the number of reports of unexpected autopilot behavior some of which are unexplained, re-assessment of this autopilot system is recommended and operators should be made aware of any problems and manufacturers analysis actions and recommendations.

## Civil Aviation Authority

5. Ensure that all operators strictly adhere to CAA regulations and requirements, especially in remote stations

Pilot Training:
Emphasis should be made in pilot training on the following:
6. Early detection and recognition of conditions that could lead to upset condition.
7. Timely and appropriate recovery action from upset conditions to counteract sudden unknown abnormal conditions.

Human Factors:
8. Recommend in depth studies of the Spatial Disorientation, ways of early recognition between crew members and appropriate crew action to overcome it and increase crew awareness of this phenomena
9. Although a level of CRM was observed, it is clear that more emphasis in this area of training will achieve earlier recognition and recovery from abnormal conditions

## MCA response to U.S. Comments

Reference: U.S. Summary Comments on Draft Final Report of Aircraft Accident<br>Flash Airlines flight 604, Boeing 737-300, SU-ZCF<br>January 3, 2004, Red Sea near Sharm El-Sheikh, Egypt

## SUMMARY:

## U.S. Comment: ${ }^{1}$

During the investigation, the accident investigative team, which consisted of Egyptian, French, and U.S. investigators, adopted a "scenario tree" methodology to determine the accident sequence of events. As part of this methodology, the investigative team identified possible accident scenarios, and sufficient evidence existed for the team to rule out most of the identified scenarios. The team then examined the remaining scenarios and the evidence collected during the investigation to determine which scenario most likely explained the accident sequence of events.

MCA response:
Both the "scenario trees" addressing the systems and the Human issues as agreed upon by the different parties participating in the accident investigation have been fully included in the report. These scenario trees which were based on factual information included in the factual report and agreed upon by all parties were used as the basis for the analysis.

The MCA's position is that the scenarios that could not be ruled out must all be considered as possibilities. Trying to speculate a more likely scenario does not comply with standard investigative practices.

## U.S. Comment:

The only scenario identified by the investigative team that explained the accident sequence of events and was supported by the available evidence was a scenario indicating that the captain experienced spatial disorientation, which resulted in his making inadvertent actions that caused the accident. The remaining scenarios and possible causes were not consistent with the evidence and did not explain the sequence of events identified by the investigative team.

Specifically, no evidence of any airplane-related malfunction or failure was found. The exhaustive examination of the 737's autopilot and lateral control systems identified no fault that could explain the airplane's motion during the accident flight. In fact, as the MCA's draft final report properly concludes, the accident airplane's motion is consistent with the flight control movements recorded on the flight data recorder.

## MCA response:

Referring to the Fault tree analysis (13.0 Right roll Continues to overbank with aileron activity), it could be noted that the analysis did not lead to the above conclusion. Also, the analysis does not

[^50]support the above U.S. statement. Had this been the case, these scenarios would have been ruled out as the rest of scenarios considered by the fault tree.
With regard to the statement that there was supporting evidence that the captain experienced spatial disorientation is inaccurate to say the least. The investigation team studied this scenario extensively, numerous conflicting evidences appeared leading to the MCA adopting the position that no conclusive evidence could be found to explain this accident

The Fault Tree that was developed and agreed upon by the participating investigation parties addressing the probable causes included in the Report are shown hereafter, including the scenarios that could not be ruled out due to their level of consistency with the available factual data.

1- Autopilot Actuator Fault (Actuator Hardover without Force Limiter 17 to 20 Ib Force) was not ruled out (refer to pages 1, 2, 9 and 11 of the fault tree)

Cairo 4 Feb 05
13.0 Right Rol Contnues to Overbank with Aileron Activity
N.B.

For the "Lateral System Fault" block, See Appendix 2-1 lateral control analysis

13.0 Right Roll Continues to Overbank with Aileron Activity

N.B.

For the "Actuator Hardover without Force Limiter 17 to 20 lb Force (SCENARIO 11)" block, See Appendix 2-1 lateral control analysis

2- Trim/Feel Unit Fault was not ruled out (refer to pages 1, 2, 17, 20 of the fault tree)

Cairo 4 Feb 05
13.0 Right Rol Contnues to Overbank with Aileron Activity
N.B.

For the "Lateral System Fault" block, See Appendix 2-1 lateral control analysis

Cairo 26 Aug 05
13.0 Right Roll Continues to Overbank with Aileron Activity

3- Spoilers wing cable jam and F/O wheel jam were not ruled out (refer to pages 1, 2, 17, 21 of the fault tree)

Cairo 4 Feb 05
13.0 Right Rol Contnues to Overbank with Aileron Activity
N.B.

For the "Lateral System Fault" block, See Appendix 2-1 lateral control analysis

13.0 Right Roll Continues to Overbank with Aileron Activity

Cairo 26 Aug 05
13.0 Right Roll Continues to Overbank with Aileron Activity

## U.S. Comment:

## SUMMARY (continue)

The MCA's draft final report stated, "no conclusive evidence could be found from the findings gathered through this investigation to determine a probable cause." Instead, the draft final report offered a list of findings, including "possible causes," even though the identification of possible causes is not consistent with international protocol concerning aviation accident investigations. Specifically, International Civil Aviation Organization Annex 13, paragraph 3.2.5, stipulates, "a list of possible causes should not be given." The report also indicated that "any combination of these findings could have caused or contributed to the accident." Three of the four possible causes identified in the MCA's draft final report were an aileron trim fault, an autopilot actuator fault, and a spoiler jam, none of which were supported by the evidence collected during the investigation.

MCA response:

- MCA does not agree with U.S. statement because, had this been the case, these scenarios would have been ruled out as well. On the contrary they were not ruled out because of their level of consistency with the available factual data.

## U.S. Comment:

## SUMMARY (continue)

The MCA' s investigation of the operational and human factors related to the accident was minimal. Further, its documentation of the captain's training history and performance and issues related to flight crew proficiency, fatigue, and crew resource management (CRM) were not fully developed and analyzed in the draft final report, despite being pertinent to the circumstances of the accident. If the MCA had obtained additional information about these areas, the investigative team could likely have identified specific corrective actions that would prevent recurrence.

MCA Response:

- The "scenario trees" addressing the Human issues as agreed upon by the different parties participating in the accident investigation have been fully included in the report. This scenario tree was used as the basis for the analysis.

## U.S. Comment:

## SUMMARY (continue)

This letter provides the U.S. investigative team's position on the cause of this accident, which is consistent with the available evidence, and an overview of the primary areas of concern with the MCA's draft final report. The attachment to this letter provides comments and suggests specific corrections, clarifications, and/or additions for each area of concern in the draft final report. As discussed further in this letter, the. U.S. investigative team concludes the following:

1. no evidence indicated that an airplane-related malfunction or failure caused or contributed to the accident,
2. the aileron inputs and the corresponding right roll precipitating the upset resulted from inadvertent flight crew inputs,
3. the captain experienced spatial disorientation as the right roll inputs occurred, (4) the first officer did not assume timely control of the airplane, and
4. the airplane remained fully controllable and responsive to the flight controls throughout the flight.

MCA Response:
Refer to the following analysis
U.S. Comments:

## 1- No evidence indicated that an airplane-related malfunction or failure caused or contributed to the accident.

To fully evaluate the role of the airplane and its systems in this accident, the investigative team relied on evidence such as cockpit voice recorder (CVR) and flight data recorder (FDR) information and flight performance and simulation evaluations. The operating aspects and potential failure modes of the various systems were also reviewed. Evidence from the investigation does not indicate that a failure of the airplane's autopilot or lateral control systems occurred. Further, during flight simulator evaluations, Egyptian, French, and U.S. investigators were able to maintain airplane control with relatively minor inputs during the demonstrations of all but one of the simulated system failures. This simulated failure involved a quintuple failure within an autopilot actuator that would result in an uncommanded roll input and require up to 80 pounds of control wheel force to overcome. FDR, CVR, and flight simulations data showed no evidence that such a failure occurred.

During subsequent meetings of the investigative team, the MCA presented numerous additional system failure scenarios for consideration. Factual evidence presented during these meetings and in follow up correspondence with the MCA and discussions between team members and MCA personnel eliminated all but two of these scenarios from consideration. The hypothetical failures that could not be fully ruled out because of a lack of associated data were the possibility that an aileron trim runaway had occurred or that an uncommanded autopilot flight control actuator hardover fault had occurred. Analysis of FDR data and simulation studies of the effects of these two failure scenarios (each of which required two or more system failures) indicated that it is highly improbable that these failures occurred. Further discussion of these two hypothetical failures follows.

Aileron trim runaway. The MCA's draft final report accurately stated that an aileron trim runaway had not occurred before the autopilot was disconnected. After the autopilot was disengaged and as the airplane continued to roll to the right, FDR data showed aileron deflection rates well in excess of the aileron trim actuator rate of $0.6^{\circ}$ per second. The rates recorded by the FDR could only have been achieved through manual wheel input because they exceeded the capabilities of the aileron trim system. Further, during flight simulations in Boeing's Multipurpose Engineering Cab (M-cab) simulator, investigators easily identified and controlled the aileron trim runaway and demonstrated that only 15 pounds of control wheel force were required to return to and maintain the aileron surfaces at the neutral position.

MCA Response:
Aileron trim runaway:
Reference:
Section 2.5.13 Right roll continues to overbank with ailerons activity, item 6.3.4.2 of the Report (Aileron Trim Runaway to 60 deg. Scenario)

Assumptions:

- One trim switch stuck at closed position (a latent failure), the second trim switch has stuck at closed position with trim input from the flying crew, leading to trim motor hardover position driving the ailerons to 15 degrees (maximum trim authority) towards right turn.
- This failure is assumed to occur after autopilot disconnect.

Consequences of the hypothetical failure:

- The aileron trim actuator will reach its hardover position driving the ailerons to 15 degrees (maximum trim authority) at no load on the aileron control wheels.
- Both aileron wheels will be driven away from the neutral position when released.
- The ailerons and flight spoilers will always follow the aileron wheels.
- The new position for the wheel will be about 65 degrees at no load on the aileron control wheels. The force-wheels relation will change (refer to Figure 2.5.13.7 Ailerons and spoilers behavior with aileron trim actuator at its hardover position)
- Whenever the aileron wheels are released, the wheels will move to the hardover position (65 degree).
- The ailerons wheels will always follow each others simultaneously.
- No cockpit light or aural warning will support identifying this fault
- The Captain and F/O will be able to resist the trim action and control the ailerons and spoilers but with additional force (Refer to Fig Figure 2.5.13.7)
- Whenever the Captain and F/O release the ailerons control wheels, the ailerons will tend to move towards right turn unless one of the flying crew exerts forces on the aileron control wheels to restore the airplane attitude.

Results of the M-Cab test (This test was done on Boeing M-Cab, Seattle, Washington):
M-Cab results confirmed the analytical studies for the failure.

This fault could not be ruled out, based on the following:

- The results obtained from the analytical studies and the M-Cab test show a very close consistency with the available data.
- The airplane behavior is consistent with the consequences of the hypothetical fault:

1. The ailerons movements towards airplane right roll are highly consistent with the expected position resulted from this hypothetical fault.
2. This fault always drive the airplane in the right roll direction
3. Movement of the aileron surfaces as shown in the FDR towards the neutral position are consistent with captain attempts to control the airplane attitude with the existence of the failure, the rate of airplane rolling to the right is always reduced with these attempts. The forces required to move the ailerons by the captain are higher than the forces required in normal condition with no fault.
4. Whenever the captain control wheel is released, the ailerons move towards the offset position showing high consistency with the fault existence. The fault was continually driving the airplane towards more right roll
5. At the end of the flight, the FDR shows considerable aileron movements towards the wing level condition, which are consistent with crew inputs (attempt) to control the airplane attitude with the existence of the failure (forces are higher than normal to overcome the centering springs). Based on evaluation in M-Cab, this event fits the data. However, trim fault must have occurred after autopilot engagement (zero force, zero aileron engagement indicates zero trim at that point). This hypothetical condition
shows close consistency with the event. This condition is also consistent with the possibility of recovering the airplane when appropriate quantity of input is applied timely on the airplane.
6. The movements of the ailerons throughout the last recovery phase highly support this scenario. The FDR data shows that even with the captain attempt to recover the airplane at the last stages, the ailerons always had the trend to move towards the opposite direction of correction which is highly consistent with the fault existence when the captain effort to restore the airplane is reduced.
7. Referring to U.S. comments, it is stated that "The rates recorded by the FDR could only have been achieved through manual wheel input because they exceeded the capabilities of the aileron trim system which is 0.6 degrees". The max rate is meaningful only if the aileron control wheels are released. If the aileron wheels are held firmly and not released, the aileron trim runaway will not cause any movement to the ailerons, only an induced increasing force will be generated on the control wheels. Wheel forces are not recorded in the FDR. The moment the aileron wheels are released, the aileron wheels and the ailerons will immediately move to the new trimmed condition. Based on the above analysis, the MCA does not agree with the U.S. comment
8. Crew behavior study does show consistency.
9. Although an attempt to correctly recover was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery within the available remaining time before impact.

AILERON AND AILERON TRIM CONTROL SYSTEM - GENERAL DESCRIPTION 2

AILERON AND AILERON TRIM CONTROL SYSTEM - COMPONENT LOCATIONS 2

## 737-300 Lateral Control System

Figure 2.5.13.7 Ailerons and spoilers behavior with aileron trim actuator at its hardover position

Ailerons Movement- FDR data

[^51]Autopilot flight control actuator hardover. The MCA's draft final report accurately stated that an aileron autopilot flight control actuator hardover most likely had not occurred. An autopilot flight control actuator can only provide an uncommanded aileron control system input if three separate faults occur simultaneously within the actuator: the arm solenoid must be commanded open, the detent solenoid must be commanded open, and the transfer valve spool must be jammed off center. This failure scenario would result in a hardover to the autopilot actuator authority limit, ultimately commanding the aileron surfaces to a maximum position of $\pm 15^{\circ}$ and the control wheel to $60^{\circ}$ (in the absence of manual input). The effects of this failure scenario were inconsistent with the FDR data. Further, during M-cab flight simulations, investigators easily identified and controlled the hardover and demonstrated that only 17 to 20 pounds of control wheel force were required to counter the hardover effects.

MCA Response:

## Reference:

Section 2.5.13 Right roll continues to overbank with ailerons activity, item 6.2.2.3.1.1 Both Solenoids and Transfer Valve Jammed (Autopilot actuator, both Solenoids and Transfer Valve Jammed (Actuator Hardover without Force Limiter 17 to 20 lb Force)) (section 2.5.13) of the Report

Assumptions:

- These faults require 3 concurrent faults. Detent solenoid was in correct position at autopilot engagement. Arm solenoid could be latent failure. Transfer was working on previous flight and could have occurred anytime after last use of autopilot and would have been latent from that point.
- Both the Arm and the Detent solenoid are assumed to fail (stuck open). The transfer valve is assumed to fail in the position commanding right bank

The cause of these failures can not be conclusively identified. However the failure of the arm solenoid (stuck open solenoid) might have been the result of a stuck closed contact (MCP engage relay A). Also these failures might be the result of an electric short within the electrical socket on the autopilot actuator.

Consequences of the hypothetical failure:

- This triple fault will result in an A/P actuator hardover.
- The crew will not be able to engage the autopilot.
- With autopilot disengaged, the affected autopilot actuator will always try to drive the ailerons and spoilers towards the actuator hardover position, driving the airplane towards airplane right roll direction. Both aileron wheels will be driven away of the neutral position and will be positioned at about 60 degrees wheel position, The Captain and the F/O will be able to control the ailerons and flight spoilers with an additional force of 17 lbs to overcome detent piston pressure and override the autopilot actuator.
- The ailerons and flight spoilers will follow movement of the ailerons control wheels.
- Whenever the control wheels are released, the control wheel will tend to return to the relevant autopilot actuator hardover position ( 60 degrees wheel position), resulting in an aileron deflection of about $\pm 13$ degrees and spoilers deflection and driving the airplane towards airplane right roll direction.
- This fault will not be associated with any visual indication or audio warning in the cockpit

Results of the M-Cab test (This test was done on Boeing M-Cab, Seattle, Washington):
M-Cab results confirmed the analytical studies for the failure. Therefore, the MCA does not agree with the U.S. comment that this is not consistent with the FDR data".

MCA agrees with the U.S. statement that "Further, during M-cab flight simulations, investigators easily controlled the hardover and demonstrated that only 17 to 20 pounds of control wheel force were required to counter the hardover effects" provided that the failure is well recognized and anticipated.."

MCA does not agree with the U.S. comment that "the fault was easily identified by the investigators" for the following reasons.

- This fault is not associated with any visual or audio warning in the cockpit.
- This failure is not included in the FCOM (Flight Crew Operating Manual)
- This failure is not included in any airplane training phase.

This fault could not be ruled out, based on the following:

- The results obtained from the analytical studies and the M-Cab test show a very close consistency with the available data.
- The airplane behavior is consistent with the consequences of the hypothetical fault:

1. The ailerons movements towards airplane right roll are highly consistent with the expected position resulted from this hypothetical fault.
2. This fault always drive the airplane in the right roll direction
3. Movement of the aileron surfaces as shown in the FDR towards the neutral position are consistent with captain attempts to control the airplane attitude with the existence of the failure, the rate of airplane rolling to the right is always reduced with these attempts. The forces required to move the ailerons by the captain are higher than the forces required in normal condition with no fault.
4. Whenever the captain control wheel is released, the ailerons move towards the offset position showing high consistency with the fault existence. The fault was continually driving the airplane towards more right roll
5. The movements of the ailerons throughout the last recovery phase highly support this scenario. The FDR data shows that even with the captain attempt to recover the airplane at the last stages, the ailerons always had the trend to move towards the opposite direction of correction which is highly consistent with the fault existence when the captain effort to restore the airplane is reduced.
6. The Captain repeated announcement "Autopilot" and the F/O announcement "Autopilot is engaged commander" support this hypothetical scenario and
indicating that the autopilot was still interfering and driving the airplane not the way it should be in the normal conditions.
7. Crew behavior study shows consistency.
8. Although an attempt to correctly recover was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery within the available remaining time before impact.

## U.S. Comment:

The MCA subsequently proposed two additional hypothetical failure scenarios: a temporary spoiler wing cable jam and a temporary first officer control wheel jam. The MCA's draft final report properly concluded that the accident airplane's motion is defined by FDR- recorded control surface deflections, including spoiler and aileron (control wheel) deflections. The effects of a temporary spoiler wing cable jam or of a temporary first officer control wheel jam would render the previous statement (and the simulation data analyses upon which it is based) false. Therefore, considering these hypothetical failure scenarios is illogical.

Further, the MCA's draft final report did not explain how the airplane got to the point in the right roll at which the temporary jams supposedly occurred. Initially, the airplane was in a left bank, but it then started banking right. The MCA proposes that the fault occurred as the airplane was increasing through a bank angle of about $25^{\circ}$; however, the airplane's initial departure from the $20^{\circ}$-left-bank attitude occurred about 45 seconds before the hypothetical faults would have started. In addition, the first officer's comment, "turning right, sir," occurred about 9 seconds before the hypothetical faults would have started.

## MCA Response:

3- Spoiler wing cable jam offset of the neutral position

## Reference:

Item 6.3.5.3.1 (section 2.5.13) of the Report Scenario 10 - Spoiler wing cable jam offset of the neutral position at time 92450 (maximum wheel deflection). and clears at 92472, the following are the Results of the M-Cab test ${ }^{3}$

Assumptions:

- The spoiler wing cable is assumed to jam offset of the neutral position at time 2:44:36 (92450 time frames in seconds). At this time the ailerons and the aileron wheels were at their maximum deflections (based on the FDR data)
- The left aileron was at 8.1 degrees (Trailing Edge Down), the right aileron was at 11.8 degrees (Trailing Edge Up). The airplane pitch angle was 11.25 degrees. The roll angle was 24.6 degrees (right roll)
- This fault is assumed to be cleared at 2:44:58 (92472 time frames in seconds) (beginning of the recovery effort.

Consequences of the hypothetical failure:

- The ailerons control wheels will, when released (no load condition) move and remain at a position equal to the position at the moment of the jam (about 40 degrees right rollFDR data) minus 12 degrees (transfer mechanism lost motion, caused by the effect of the feel and centering spring), resulting in about 28 degree wheel deflection in the right

[^52]roll direction. This corresponds to about 7 degrees of aileron deflections. (considering ailerons offset).

- "The flight spoilers will remain in the position corresponding to the position of the jammed spoilers wing cables, irrespective of any mechanical inputs from either control wheel (about 12 degrees- FDR data).
- The ailerons can still be controlled via the captain's wheel. However, movement of aileron wheel towards airplane left turn (to correct for the right bank tendency) will be opposed by the override mechanism spring, consequently the forces required to move the ailerons in this direction will be significantly higher than the normal forces at no fault (about 50 lbs additional force)
- The F/O will not be able to control the ailerons in the direction of airplane left turn, with limited ability to control it in the direction of airplane right turn.
- This fault will not be associated with any visual indication or audio warning in the cockpit

Results of the M-Cab test (This test was done on Boeing M-Cab, Seattle, Washington):
The simulations take into account the effects of blowdown on the ailerons. However, the blowdown effects on the spoilers are not included because of the way in which these hypothetical faults were simulated.

The longitudinal plot includes the following parameters:

- Press Altitude (Feet)
- Airspeed (Knots)
- Right engine N1 (\%)
- Longitudinal acceleration (g's)
- Air/ Ground switch
- Autopilot status
- Pitch attitude (Degrees)
- Body angle of attack (Degrees)
- Column deflection (Degrees)
- Elevator deflection (Degrees)
- Stabilizer position (Units)
- Normal load factor (g's)
- Right main gear down
- Flap detent (Degrees)

The lateral plot includes the following parameters:

- Press Altitude
- Airspeed (Knots)
- Right engine N1 (\%)
- Roll attitude (Degrees)
- Wheel force (lbs)
- Control wheel deflection (Degrees)
- Left aileron deflection (Degrees)
- Right aileron deflection (Degrees)
- Left spoiler deflection (Degrees)
- Right spoiler deflection (Degrees)
- Lateral acceleration (g's)
- Magnetic heading (Degrees)
- Rudder deflection (Degrees)

Figu
re 2.5.13.15a Scenario 10 - Spoiler wing cable jam (longitudinal parameters)

Figure 2.5.13.15b Scenario 10 - Spoiler wing cable jam (lateral parameters)

As shown from the two plots, the results obtained from the M-Cab test show a very close consistency with the FDR data which may explain this event. The estimated aileron wheel forces needed to move the wheel to correct for the right turn tendency is $\sim 50 \mathrm{lbs}$.

In response to the comment "The MCA's draft final report properly concluded that the accident airplane's motion is defined by FDR- recorded control surface deflections, including spoiler and aileron (control wheel) deflections. The effects of a temporary spoiler wing cable jam or of a temporary first officer control wheel jam would render the previous statement (and the simulation data analyses upon which it is based) false", the statement is incorrect due to the close consistency showed in above.

This fault could not be ruled out, based on the following:

- The results obtained from the analytical studies and the M-Cab test show a very close consistency with the available data.
- The airplane behavior is consistent with the consequences of the hypothetical fault:

1. The spoiler wing cable jams offset of the neutral position at time 2:44:36 (92450 time frames in seconds) and clears at 2:44:58 (92472 time frames in seconds, beginning of the recovery effort).
2. The ailerons movements towards airplane right roll are highly consistent with the expected position resulted from this hypothetical fault.
3. This fault always drive the airplane in the right roll direction
4. Movement of the aileron surfaces as shown in the FDR towards the neutral position are consistent with captain attempts to control the airplane attitude with the existence of the failure, the rate of airplane rolling to the right is always reduced with these attempts. The forces required to move the ailerons by the captain are considerably higher than the forces required in normal condition with no fault.
5. Whenever the captain control wheel is released, the ailerons move towards the offset position showing high consistency with the fault existence. The fault was continually driving the airplane towards more right roll
6. The movements of the ailerons throughout the last recovery phase highly support this scenario. The FDR data shows that even with the captain attempt to recover the airplane at the last stages.
7. In the analysis in section 2.5.11 studying the chronological event where the airplane stopped the left turn and started a right turn at about 92420, the pilot input probability was not ruled out as one of the possible causes for this event. The analysis in section 2.5.11 concluded that is not possible to determine a higher possibility to any of the mentioned possibilities based on the given data4 including the pilot input.
[^53]This explains how the airplane got to the point in the right roll at which the temporary jams supposedly occurred.
8. It is expected that wheel forces with higher magnitude can affect the speech pattern, however, it is noticed that there were no captain speeches when the ailerons were near to their neutral position, most of the speeches were made at the timing where the ailerons were moving back to their position relevant to spoilers cables jammed condition. The timing and length of the Captain speeches through this event does not provide sufficient information to verify the effect of this force on the speech tone
9. Crew behavior study shows consistency
10. Although an attempt to correctly recover was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery within the available remaining time before impact.

4- Temporarily, First Officer wheel jam (offset of the neutral position) at time 92450 (maximum wheel deflection), and clears at 92472

Assumptions:

- The F/O wheel jam is assumed to jam offset of the neutral position at time 2:44:36 (92450 time frames in seconds). At this time the ailerons and the aileron wheels were at their maximum deflections (based on the FDR data)
- The left aileron was at 8.1 degrees (Trailing Edge Down), the right aileron was at 11.8 degrees (Trailing Edge Up). The airplane pitch angle was 11.25 degrees. The roll angle was 24.6 degrees (right roll)
- This fault is assumed to be cleared at 2:44:58 (92472 time frames in seconds) (beginning of the recovery effort.

Consequences of the hypothetical failure:

- The ailerons control wheels will, when released (no load condition) remain at a position equal to the position at the moment of the jam (about 40 degrees right roll-FDR data). This corresponds to about 10 degrees of aileron deflections (considering ailerons offset).
- The flight spoilers will remain in the position corresponding to the position of the jammed spoilers wing cables (about 12 degrees- FDR data), however the captain will have a limited control on the spoilers within the transfer mechanism lost motion gap ( $\pm 12$ degree) of aileron wheel deflection.
- The ailerons can still be controlled via the captain's wheel. However, movement of aileron wheel in either directions will be opposed by the override mechanism spring, consequently the forces required to move the ailerons in both directions will be significantly higher than the normal forces at no fault (about 50 lbs additional force)
- The F/O will not be able to control the ailerons nor the spoilers in either direction.
- This fault will not be associated with any visual indication or audio warning in the cockpit

Results of the M-Cab test (This test was done on Boeing M-Cab, Seattle, Washington):
The simulations take into account the effects of blowdown on the ailerons. However, the blowdown effects on the spoilers are not included because of the way in which these hypothetical faults were simulated.

The longitudinal plot includes the following parameters:

- Press Altitude (Feet)
- Airspeed (Knots)
- Right engine N1 (\%)
- Longitudinal acceleration (g's)
- Air/ Ground switch
- Autopilot status
- Pitch attitude (Degrees)
- Body angle of attack (Degrees)
- Column deflection (Degrees)
- Elevator deflection (Degrees)
- Stabilizer position (Units)
- Normal load factor (g's)
- Right main gear down
- Flap detent (Degrees)

The lateral plot includes the following parameters:

- Press Altitude
- Airspeed (Knots)
- Right engine N1 (\%)
- Roll attitude (Degrees)
- Wheel force (lbs)
- Control wheel deflection (Degrees)
- Left aileron deflection (Degrees)
- Right aileron deflection (Degrees)
- Left spoiler deflection (Degrees)
- Right spoiler deflection (Degrees)
- Lateral acceleration (g's)
- Magnetic heading (Degrees)
- Rudder deflection (Degrees)

Figure 2.5.13.16a Scenario 10a - F/O wheel jam (longitudinal parameters)

As shown from the two plots, the results obtained from the M-Cab test show a very close consistency with the FDR data which may explain this event. The estimated aileron wheel forces needed to move the wheel to correct for the right turn tendency is $\sim 50 \mathrm{lbs}$.

In response to the comment "The MCA's draft final report properly concluded that the accident airplane's motion is defined by FDR- recorded control surface deflections, including spoiler and aileron (control wheel) deflections. The effects of a temporary spoiler wing cable jam or of a temporary first officer control wheel jam would render the previous statement (and the simulation data analyses upon which it is based) false", the statement is incorrect due to the close consistency showed in above..

This fault could not be ruled out, based on the following:

- The results obtained from the analytical studies and the M-Cab test show a very close consistency with the available data.
- The airplane behavior is consistent with the consequences of the hypothetical fault:

1. The First Officer wheel jams offset of the neutral position at time 2:44:36 (92450 time frames in seconds) and clears at 2:44:58 (92472 time frames in seconds, beginning of the recovery effort).
2. The ailerons movements towards airplane right roll are highly consistent with the expected position resulted from this hypothetical fault.
3. This fault always drive the airplane in the right roll direction
4. Movement of the aileron surfaces as shown in the FDR towards the neutral position are consistent with captain attempts to control the airplane attitude with the existence of the failure, the rate of airplane rolling to the right is always reduced with these attempts. The forces required to move the ailerons by the captain are considerably higher than the forces required in normal condition with no fault.
5. Whenever the captain control wheel is released, the ailerons move towards the offset position showing high consistency with the fault existence. The fault was continually driving the airplane towards more right roll
6. The movements of the ailerons throughout the last recovery phase highly support this scenario. The FDR data shows that even with the captain attempt to recover the airplane at the last stages.
7. In the analysis in section 2.5.11 studying the chronological event where the airplane stopped the left turn and started a right turn at about 92420, the pilot input probability was not ruled out as one of the possible causes for this event.

The analysis in section 2.5.11 concluded that is not possible to determine a higher possibility to any of the mentioned probabilities based on the given data ${ }^{5}$

[^54]including the pilot input.
This explains how the airplane got to the point in the right roll at which the temporary jams supposedly occurred.
8. It is expected that wheel forces with higher magnitude can affect the speech pattern, however, it is noticed that there were no captain speeches when the ailerons were near to their neutral position, most of the speeches were made at the timing where the ailerons were moving back to their position relevant to spoilers cables jammed condition. The timing and length of the Captain speeches through this event does not provide sufficient information to verify the effect of this force on the speech tone
9. Crew behavior study shows consistency
10. Although an attempt to correctly recover was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery within the available remaining time before impact.

## Faults Contributing Factors:

The following contributing factors apply for the hypothetical faults:

- The faults were not associated with any visual indication or audio warning in the cockpit.
- The faults were not included in the FCOM (Flight Crew Operating Manual)
- The faults were not included in any training phase.
- There were no outside visual cues
- Although an attempt to correctly recover was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery within the available remaining time before impact.

## U.S. Comments:

## 2. The aileron inputs and corresponding right roll precipitating the upset resulted from flight crew inputs.

The MCA's draft final report correctly stated that FDR data and flight simulation analyses of the 737 showed that the lateral control inputs required to reproduce the airplane's recorded motion closely matched the aileron deflections recorded on the FDR. As discussed in the previous section, the data were not consistent with a jam or runaway of the aileron actuators or a spoiler or control wheel jam; rather, the data revealed that the ailerons remained active and available until the end of the recording. The airplane's left and right roll inputs, including the maximum right roll of $111^{\circ}$, resulted from left and right wing aileron surface deflections during the time in which the autopilot was disengaged. The evidence indicates that the aileron inputs were commanded by the flight crew.

MCA Response:
With reference to the previous MCA analysis, it is clear that the referred to scenarios are still consistent with the FDR data.

MCA agrees with the U.S. comment "the data revealed that the ailerons remained active and available until the end of the recording". However, with the existence of any of the technical faults scenarios included in the report, the pilot will need additional higher forces compared to the normal conditions at no failures to be able to control the ailerons, and that "The airplane's left and right roll inputs, including the maximum right roll of $111^{\circ}$, resulted from left and right wing aileron surface deflections during the time in which the autopilot was disengaged." This statement supports the MCA conclusion regarding these scenarios.

MCA does not agree with the U.S. comment "The evidence indicates that the aileron inputs were commanded by the flight crew". This is highly speculative and not the only possible indication of this action.

All the technical failures included in the Report (Conclusion section) result in aileron movement towards right airplane roll. Movement of the aileron surfaces as shown in the FDR towards the neutral position are consistent with captain attempts to control the airplane attitude with the existence of the failure.

## U.S Comment:

## 3. The captain experienced spatial disorientation as the right roll inputs occurred.

Investigators sought to understand how a professional flight crewmember could have initiated and sustained the manual flight control inputs that resulted in the unintentional loss of the airplane. Available evidence suggests that the captain guided the airplane into an overbanked, airplane-nose-down attitude because he lost spatial orientation during the departure. Evidence consistent with factors that can contribute to spatial orientations were present before the crash. This evidence includes the following:

1. dark night conditions,
2. misleading vestibular cues,
3. flight crew distraction, and
4. inappropriate control inputs.

Dark night conditions. At the time of the accident, dark night, visual meteorological conditions prevailed. The only external visual references were lighted areas on the coast near Sharm EI-Sheikh. Soonl.after takeoff, the airplane passed over the coastline, and these external visual references were no longer visible to the flight crew.

Misleading vestibular cues. Studies performed by U.S. and French authorities, which were conducted at the MCA' s request, revealed that the vestibular sensations experienced by the flight crew would have been misleading throughout much of the flight. The flight crew's vestibular systems would have provided them with little or no information about the changes in the airplane's bank angle until after the right bank angle exceeded $30^{\circ}$ because the gradual changes in the airplane's attitude would have been below the threshold of perception. As the airplane became fully involved in the right overbank and the angle of the bank continued to increase, the vestibular sensations of the bank angles would have underrepresented the actual bank angles, and the flight crew might even have felt brief vestibular sensations leading them to perceive that the airplane was banked slightly to the left. These findings indicate that, after the airplane passed over the coast and the external visual cues were lost, the captain could only have maintained an accurate awareness of flight attitude by continuously monitoring the attitude indications on his flight instruments.

Distraction. A few seconds before the captain called for the autopilot to be engaged, the airplane's pitch began increasing and airspeed began decreasing. These deviations continued during and after the autopilot engagement/disengagement sequence. The captain ultimately allowed the airspeed to decrease to 35 knots below his commanded target airspeed of 220 knots and the climb pitch to reach $22^{\circ}$, which is $10^{\circ}$ more than the standard climb pitch of about $12^{\circ}$. During this time, the captain also allowed the airplane to enter a gradually steepening right bank, which was inconsistent with the flight crew's departure clearance to perform a climbing left turn. These pitch, airspeed, and bank angle deviations indicated that the captain directed his attention away from monitoring the attitude indications during and after the autopilot disengagement process. .

Changes in the auto flight system's mode status offer the best explanation for the captain's distraction. The following changes occurred in the auto flight system's mode status shortly before the initiation of the
right roll: (1) manual engagement of the autopilot, (2) automatic transition of roll guidance from heading select to 9 control wheel steering-roll (CWS-R), (3) manual disengagement of the autopilot, and (4) manual reengagement of heading select for roll guidance.
The transition to the CWS-R "mode occurred in accordance with nominal system operation because the captain was not closely following the flight director guidance at the time of the autopilot engagement. The captain might not have expected the transition, and he might not have understood why it occurred. The captain was probably referring to the mode change from command mode to CWS-R when he stated, "see what the aircraft did?," shortly after it occurred. The available evidence indicates that the unexpected mode change and the flight crew's subsequent focus of attention on reestablishing roll guidance for the auto flight system were the most likely reasons for the captain's distraction from monitoring the attitude indications.

According to CVR information, 24 seconds elapsed after the airplane entered the right bank before either flight crewmember acknowledged or attempted to correct the steepening right bank. However, as the airplane-was rolling from $16^{\circ}$ to $40^{\circ}$ right bank, the first officer stated, "turning right sir," and the captain replied, "what?" The first officer repeated, "aircraft is turning right," and the captain asked, "ah...turning right...How turning right?" The surprise evident in the captain's responses to the first officer's announcements about the airplane's attitude indicate that he was distracted from monitoring the attitude indications for at least 24 seconds after entering the right bank.

Inappropriate control inputs. The control wheel inputs made by the captain after the first officer told him about the right turn indicate that the captain had become spatially disoriented and that he had experienced some delay in reacquiring an accurate sense of his (and the airplane's) orientation with respect to the Earth's surface.

An appropriate response to the first officer's advisories about the right turn would have been for the captain to direct his attention to the attitude indications, confirm the airplane's attitude, and apply sufficient left control wheel force to stop the right roll and sustain a roll back toward the left. However, such corrective inputs did not begin until 17 seconds after the flight crew's exchange about the right turn. Instead, the captain made inappropriate, oscillating control wheel inputs, with rightward control wheel inputs being dominant, which caused the airplane to roll to a right bank angle of $111^{\circ}$ and a pitch attitude of $46^{\circ}$ airplane nose down.
The persistent inappropriate nature of the captain's right control wheel inputs suggest that he was unable to immediately regain an accurate awareness of spatial orientation. Studies indicate that pilots may require some time to recover from an unknown attitude and transition to stable instrument flight after a lengthy period of distraction from flight instruments. Investigations of roll upset accidents and incidents involving commercial airline flights have also revealed that from 4 to 18 seconds may elapse between the time that a pilot becomes aware of a problem with airplane attitude and the time that sustained, appropriate control wheel inputs begin.

MCA Response:
With reference to section 2.6. Crew Behavior, Report, the study performed by a team of qualified Human Performance Specialists has come up with findings summerized as follows:

- An event starting from the time of call for autopilot engagement through the time of the captain statement "see what the aircraft did" caused obvious crew distraction. This distraction may have developed to Spatial Disorientation (SD) to the captain until the time the F/O announced "A/C turning right " and acknowledged by the captain.
- There are conflicting signals in the following period of time ( $\sim 17$ seconds), it is unclear whether the captain remained in SD or was the crew unable to perceive the cause that was creating an upset condition until the time when the F/O announced that there was no A/P in action.
- After the time when the F/O announced "no A/P commander" the crew behavior suggests that recovery attempts were consistent with expected crew reaction, evidences show that the the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

## U.S Comment:

## 4. The first officer did not assume timely control of the airplane.

The first officer's lack of assertiveness during the accident sequence indicated that he had inadequate CRM skills. The first officer's verbal communications indicated that he had an accurate awareness of the airplane's flight attitude during the upset sequence. However, he did not escalate his assertiveness to prevent the captain from overbanking the airplane to the right. The first officer could have offered suggestions, issued commands, or attempted to take control of the airplane. Instead, as the airplane's bank angle exceeded $40^{\circ}$, the first officer began repeatedly calling out, "overbank," and issuing routine responses to the captain's requests for autopilot engagement.

## MCA Response:

MCA does not agree with the U.S. comment. All evidences extracted from the FDR and CVR do not support this statement. On the contrary, the first officer's verbal communications indicated that he had an accurate awareness of the airplane's flight attitude during the upset sequence. MCA analysis of the crew behavior (F/O and Observer) indicate that actions taken in the cockpit did not call for any additional intervention supporting the view that the PF was counteracting some unusual condition..

## U.S Comment:

Differences in flight crewmember status. Disparities between the captain's and first officer's aviation experience likely produced differences in perceived status between the two men, which might have reduced the first officer's willingness to escalate his assertiveness to the point of taking control of the airplane. The 53 -year-old captain had been a pilot for over 35 years, held an airline transport pilot certificate, and had accumulated about 7,400 flight hours. He had retired from the Egyptian Air Force in 2000 with the rank of Air Vice Marshal (equivalent to a U.S. brigadier general). He had served as a pilot and flight instructor in high-performance military jets, and he had flown as pilot-in-command on four different types of transport-category airplanes. The 25-year-old first officer had been a pilot for 7 years, held a commercial pilot certificate, and had accumulated about 800 flight hours. The first officer had no prior experience with transport-category airplanes before joining Flash Airlines.

## MCA Response:

MCA does not agree with the above U.S. comment. Based on the factual information regarding both the cockpit crew members included in "Chapter 1 (Factual Information), Sections 1.5.1 and 1.5.2, Final Report", both cockpit crew members were satisfying all the regulatory requirements. In addition, it is quite normal to have a captain that is older than the first officer with higher flying experience and in this case a positive response of the F/O indicating airplane turning right and overbank clearly shows that he was not negatively influenced by authority gradient. Also the observer pilot ( 43 years old, 4000 flying hours, U.S. license holder) reaction also supports that actions in the cockpit did not require any intervention with the PF

Flash Airlines CRM training. Many previous accidents have occurred when captains' errors went unchallenged by first officers. Aviation studies have provided further evidence about the role of poor CRM in accidents and about the importance of emphasizing CRM skills in airline training. Guidelines for CRM training encourage carriers to train their pilots how to promote a course of action they feel is best, even if it involves conflict with others. This is a difficult issue for many carriers, because encouraging flight crewmembers to challenge a captain's authority could increase disagreements between flight crewmembers, potentially creating a new set of safety concerns. However, the accident record suggests that safety benefits may be obtained by encouraging first officers to be appropriately assertive if a captain does not appropriately address an imminent threat to flight safety.

Flash Airlines' training manual contained a CRM ground training course outline marked,
effective January 2, 2003." The manual stated that CRM training would be provided to pilots during initial and recurrent training and would consist of 12 hours of instruction over 2 days. One of the topics included in this training was "communication skills of inquiry, advocacy, and feedback." The airline's Flight Operations Manual stated, "During flying training on aeroplanes with a flight crew of 2 particular emphasis will be placed on the practice of Line Orientated Flying Training (LOFT) with emphasis on Crew Resource Management (CRM) and the use of correct crew coordinated procedures." Despite the existence of these documents and policies, the MCA's report stated that Flash Airlines did not provide CRM training to either of the accident pilots. Therefore, the first officer did not receive training in skills that could have helped him playa more active role in the airplane's recovery.

## MCA Response:

It is to be noted that the CRM training was not mandatory at the time of the accident. MCA believes that, although a level of CRM was observed, it is clear that more emphasis in this area of training will achieve earlier recognition and recovery from abnormal conditions

## U.S Comment:

## 5. The airplane remained fully controllable and responsive to the flight controls throughout the flight.

Analysis of the FDR data revealed that the airplane remained controllable throughout the entire flight. The maximum recorded bank and pitch angles during the airplane's descent were about $111^{\circ}$ right wing down and $46^{\circ}$ airplane nose down, respectively. As a result of flight crew corrective roll and pitch inputs, the airplane began to recover; however, the recovery attempt began too late to prevent the accident. FDR data indicated that, just before impact, the bank and pitch angles had decreased to about $14^{\circ}$ right wing down and $23^{\circ}$ oirplane nose down, respectively.

MCA Response:
MCA agrees with the U.S. remark that the analysis of the FDR data revealed that the airplane remained controllable, on condition that any failure condition was correctly perceived and timely correction applied.
U.S. Comment:

CONCLUSIONS

In summary, the evidence collected during this c investigation strongly supports the conclusions that no airplane-related malfunction or failure caused or contributed to the accident and that the accident can be explained by the captain's spatial disorientation and the first officer's failure to assume timely control of the airplane.

MCA response:

An event starting from the time of call for autopilot engagement through the time of the captain statement "see what the aircraft did" caused obvious crew distraction. This distraction may have developed to Spatial Disorientation (SD) to the captain until the time the F/O announced "A/C turning right "and acknowledged by the captain.
There are conflicting signals in the following period of time ( $\sim 17$ seconds), it is unclear whether the captain remained in SD or was the crew unable to perceive the cause that was creating an upset condition until the time when the F/O announced that there was no A/P in action. After the time when the F/O announced "no A/P commander" the crew behavior suggests that recovery attempts were consistent with expected crew reaction, evidences show that the the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

MCA believes that the, with reference to section 3 Conclusion of the report, the possible accident causes are as follows:

- Trim/ Feel Unit Fault (Aileron Trim Runaway)
- Temporarily, Spoiler wing cable jam (Spoiler offset of the neutral position)
- Temporarily, F/O wheel jam (spoilers offset of the neutral position)
- Autopilot Actuator Hardover Fault

Possible contributing factors are as follows:

- A distraction developing to Spatial Disorientation (SD) until the time the F/O announced "A/C turning right" with acknowledgement of the captain.
- There are conflicting signals which make unclear whether the captain remained in SD or was the crew unable to perceive the cause that was creating an upset condition until the time when the F/O announced that there was no A/P in action
- After the time when the F/O announced "no A/P commander" the crew behavior suggests the recovery attempt was consistent with expected crew reaction, evidences show that the corrective action was initiated in full, however the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

# U.S. Detailed Comments on Draft Final Report of Aircraft Accident <br> Flash Airlines flight 604, Boeing 737-300, SU-ZCF <br> January 3, 2004, Red Sea near Sharm El-Sheikh, Egypt 

## FACTUAL ${ }^{6}$

U.S. Comment:

Page 24, Section 1.5.1.2., Background information, ii

The third bullet point notes the captain's work experience at Scorpio Aviation.
This section and elsewhere, as appropriate, should address the apparent shortcomings with the captain's ATR 42 training and/or records (the captain did not meet ATR training minimums recommended by the airplane manufacturer, and the draft final report does not establish how these compared to ECAA minimum requirements). It also appears that some of the captain's ATR flight training was performed during passenger flights.

Page 24, Section 1.5.1.2., Background information, ii
The fourth bullet point should correct the accident date to be 3 January 2004.

## MCA Response

## Corrected

## U.S. Comment:

Page 24, Section 1.5.1.2., Background information, v

Section v currently reads:
History of position flown for specific aircraft, and dates of upgrades (i.e., copilot to captain)
Refer to page 14 of the Factual Report
Information on the captain's positions flown (i.e., flight engineer, first officer, captain) for specific airplanes and dates of his position upgrades (in the military and in civil aviation) should be inserted or referenced here. This information is not contained on $p$. 14.

Page 24, Section 1.5.1.2., Background information, vi

[^55]Section vi is currently titled:
"All" captain's training records (including his last recurrent training).
Records documenting the captain's hours of Boeing 737 ground training and Flash Airlines company indoctrination training should be included in the pages of training records that follow page 24 . Such records were included for the first officer. If such records are unavailable for the captain, this should be explained.

## Page 1 of 40

## MCA Response:

Added

## U.S. Comment:

Page 61, Section 1.5.1.7., Additional factual documentation (Captain)
A note at the bottom of the page states that the captain took a deadhead flight from CAI to SSH on January 1, 2004.

This section should list other deadheading flights by the captain during the period covered by the table.

## MCA Response:

## Adopted

U.S. Comment:

Page 63, Section 1.5.1.7., Additional factual documentation (Captain)
The first paragraph on this page states:
The captain's time on Russian aircraft (MiG-21). Hercules transport aircrafts C130 (dates and number of hours). ADI display configuration in comparison with B737-300 ADI display. Refer to captain CV, and item 1.5.1.2 (vi)

Neither the captain's C.V. nor his training records contain this information.
The captain's flight experience on MiG-21 and C-130 airplanes and a comparison of their attitude displays with the displays of the accident airplane should be provided here.

## MCA Response:

Captain flew approximately in this sequence:
Russian Mig: 1000 flying hours (Russian ADI display)
C130: 5000 hours (Conventional ADI display)
ATR: 700 hours (Conventional ADI display)
Boeing 737: 700 hours (Conventional ADI display)

## U.S. Comment:

Page 65, Section 1.5.2.2., Background information
Section i of this page, titled "Beginning of his flying career" summarizes the first officer's Boeing 737-300 initial training. It states:

- The F/O began his ground training on the aircraft type 737-300 at Luxor Airway from 4 May 2002 to 16 May 2002
- The F/O completed the Full Flight Simulator Training and the Flight Training at Flash Airline on 30 June 02

Section 1.17.2.1, page 312, states that a January 2003 ECAA audit found Flash Airlines
had no training program. Information should be provided here describing the training program used for the first officer's May 2002 Boeing 737 ground training.

The first officer's initial simulator proficiency check form, dated June 30, 2002 states that a Boeing 737-300/400/500 simulator was used. Information should be provided about which variant the simulator was configured to represent, and whether the first officer received any differences training for the 300/400/500 variants.

## MCA Response:

Note: (added)
Luxor Air training forms are approved training syllabus by ECAA. The audit of Flash Airline carried on January 2003 comment that Flash was still using training forms under the name of the previous operator who was also ECAA approved but they should change the forms to the name of Flash.
U.S. Comment:

Page 76, Section 1.5.2.2., Background information
This page contains a copy of the first officer's training record titled "Proficiency Check Form," dated July 02. A notation on the document says it is page 1 of 2 , but the second page is not included. It states that it is from the flight training department of Heliopolis

Airlines, and that the first officer's proficiency check was conducted in a Flash Airlines airplane. MCA has added a notation to the bottom of the page stating that Flash Airlines took over some of the Heliopolis Airlines routes, but this does not explain the use of Heliopolis training forms.

Information should be provided about whether Flash Airlines was utilizing the training program of Heliopolis Airlines and whether the use of Heliopolis training forms by Flash Airlines was acceptable under ECAA regulations.

## MCA Response:

## Added

## U.S. Comment:

Page 97, Section 1.5.2.3., 72-hour history of the F/0
This section refers the reader to pages 72 and 73 of the factual report for information on the F/O's 72 -hour history. Neither pages 72 and 73 of the factual report, nor pages 72 and 73 of the draft final report provide a narrative description of the first officer's activities in the 72 hours before the accident.

The first officer's work schedule and any other known activities in the 72 hours before the accident should be summarized here in a narrative format.

## Page 107, Section 1.6.2.1 Electronic Attitude Direction Indicator (EADI)

Some of the original text for the description of the EADI is missing. The original text stated:

The artificial horizon line which separates the upper blue portion of the display from the lower brown portion moves up and down as the airplane pitches and tilts.

The sentence should read:
The artificial horizon line which separates the upper blue portion of the display from the lower brown portion moves up and down as the airplane pitches and tilts left and right as the airplane rolls.

## MCA Response:

## Adopted

## U.S. Comment:

Page 120, Section 1.6.6.3, section C
This section states:
On January 3rd, 2003, aircraft SU-ZCF, a daily check was performed in accordance with the approved checklist as per the company maintenance
schedule at SSH station just before the flight. The check was carried out by the accident flight on board engineer.

Date should be changed to 3 January 2004, not 2003. The report should clarify how it is known that this check was completed, as the maintenance records were reportedly lost with the aircraft.

MCA Response:

## Adopted

U.S. Comment:

Page 121, Section 1.6.6.4, The maintenance log sheets for the flights after 12/31/03

Page 3 of 40

## This section states:

Lost on board and no copies prior to departures from SHH which is a violation of ECAA regulations. Necessary measures are taken by ECAA to ensure adherence.

The specific ECAA regulations that apply should be provided here, as well as the steps taken by ECAA to ensure adherence.

## U.S. Comment:

Page 121, Section 1.6.6.5, The lack of write-ups on the TOGA problem and slat indication that existed on the entire 25 -hours of FDR

This section states:
Status of the technical log is not known due to being lost on board
The Flash Air chief pilot stated during the investigation that the airline was aware of the problem and had established a work-around procedure. The report should note this here and discuss why the TOGA problem was not addressed.

## MCA Response:

Note:

The pages lost on board covers 25 hours

## U.S. Comment:

Page 133, Section 1.10, Aerodrome Information
This section states, in part:
Clearance was provided to the accident flight crew while on the ground and the departure included a left turn at pilot's discretion and to climb to Flight Level (FL) 140 and to intercept the 306 VOR radial. MEA for this sector is 10500 ft .

The report should clarify the existence of various published minimum altitudes in the area of SSH. The report does not include any enroute charts showing Minimum Enroute Altitudes (MEA) in the vicinity of SSH. Commercially available charts for the area indicate that the MEA along the A411 airway, which is defined by the 306 radial of the SSH VOR is 12,000 feet. The SSH minimum radar vectoring altitude chart on p. 126 of the report (Section 1.8.1) indicates that a minimum radar vectoring altitude of 10,500 DME begins many miles to the northwest of the VOR.

## U.S. Comment:

Page 142, Section 1.13.1, Egyptian Air Force - Medical Board Report
This section states, in part:

1. Sequence of medical records
a) Medically fit for all flying duties as from his first medical examination dated 30/05/1970.
b) Amend to be medically fit for all flying duties to be reexamined every sis months as of 14/07/1982.
c) Amend to be medically fit for all flying duties (remove six months restriction) as of 22/04/1985.

Page 4 of 40

The report should explain the reason for the amendment that required the captain to be medically re-examined every six months from July 1982 until April 1985.

## U.S. Comment:

Page 142, Section 1.13.1, Egyptian Air Force - Medical Board Report
This section states, in part:
During Service A.F. Pilots are subjected to the following:
a) Tests for Spatial Disorientation as part of his routine periodic physical examination.
b) Sessions of physiologic training which include:

- Sudden Decompression.
- Certificate.
- Spatial Disorientation Training Chair.

A detailed description of the purpose and nature of the captain's prior spatial disorientation tests and training, referenced here, should be added to the report.
U.S. Comment:

Page 146, Section 1.13.2. Medical factors related to SD (Spatial Disorientation)
Section $C$ of this page states:
C- Medical records for the captain related to any of the conditions conducive to spatial disorientation.
No report found
A description of the types of medical conditions conducive to spatial disorientation that were considered during this search should be inserted here.

## MCA Response:

No conditions inducive of spatial disorientation recorded

## U.S. Comment:

## Page 153, Section 1.16.1, Section F

The spoiler control drum jam and control wheel shaft jam scenarios were not evaluated in the MCAB. These cases were accomplished by "background" simulation analysis.

Boeing/ Honeywell proprietary information and will not be available for public use"
Boeing and Honeywell were unable to locate a file by this name.

MCA Response:
The unidentified file had been mailed to Boeing
U.S. Comment:

Pages 270-281,1.16.2., Tests and researches conducted by NTSB

This section contains PowerPoint slides from a presentation prepared for the MCA by an NTSB investigator.

The name of the NTSB investigator should be removed from the report, and the Powerpoint slides should be replaced with a brief description of the method used for this study and a description of its findings.

MCA Response:

## Adopted

U.S. Comment:

Pages 283-303, Section 1.16.4., Tests and researches conducted by MCA
This section contains general information on spatial disorientation that appears to have been copied verbatim from a U.S. Army Field Manual, FM 3-04.301, Aeromedical Training for Flight Personnel.

Suggest that the original source for this material be identified and cited in the report. Suggest that relevant information from this source be summarized in a brief format, rather than including the entire document.

MCA Response:

## Adopted

U.S. Comment:

Page 304, Section 1.16.4., Tests and researches conducted by MCA

Any information contained in the various documents cited on this page that the MCA believes is of particular relevance to this accident should be summarized in a narrative format.

## U.S. Comment:

Page 312, Section 1.17.2.1 Safety oversight carried out on Flash Airline during the period from 2 Jan, 2003 to 16 Jan 2003 before AOC renewal

The table on this page labeled "Operation Findings" states:
Findings: There is no Training Program
Actions Taken: Training Program is submitted and approved

The report should explain how the airline had originally received its AOC when it had no training program.

MCA Response:

## Refer to previous note about Flash Airline previous operator

U.S. Comment:

Page 312, Section 1.17.2.1 Safety oversight carried out on Flash Airline during the period from 2 Jan, 2003 to 16 Jan 2003 before AOC renewal

The table on this page labeled "Operation Findings" states:
Findings: There are no DRM \&CRM Training course performed for cockpit crews, dispatchers and cabin crews
Actions Taken: The Airline has introduced a training plan starting on Sep 2003 to be done in PAS Airline

It is suggested that this section include some explanation as to why the accident pilots did not receive this training.
U.S. Comment:

Page 312, Section 1.17.2.1 Safety oversight carried out on Flash Airline during the period from 2 Jan, 2003 to 16 Jan 2003 before AOC renewal

The table on this page labeled "Operation Findings" states:
Findings: By reviewing the A/C log book sheets found that, some sheets not filled out and other some have missed data
Actions Taken: The airline issued circular for all cockpit crews and maintenance staff to strictly comply with log book sheets filling out instructions

Because of other similar findings during the accident investigation, it is suggested that
further detail about the circular and any additional action by the airline or the ECAA be provided.
U.S. Comment:

Page 313, Section 1.17.3.1, Flash Airlines procedures regarding use of autopilot when recovering from unusual attitudes

This section states:

## Refer to Flash Airline FOM (Ops Group)

Relevant information from the Flash Airlines FOM should be summarized and included in this section.

## U.S. Comment:

Pages 320-323, Section 1.17.3.8 Egyptian requirements for the training of pilots at an airline such as Flash Airlines

This section contains excerpts from the Egyptian Ministry of Civil Aviation Training Standards Handbook.

Information relevant to the flight crew and the type of operation involved in the accident should be extracted from these materials and summarized in the report.

The report should also state whether the captain met the ECAR airplane group experience requirements of 2500 hours on turbo-jet powered aircraft $>5,700 \mathrm{~kg}$ (as stipulated in the report on p . 323) prior to being initially certified as PIC for Part 121 Air Taxi flights utilizing Group IILJ aircraft. Information contained in the draft final report indicates that the captain may have only acquired 1,009 hours of jet experience (on L-29, Mig 17, and Mig 21 airplanes) by the time he was hired by Flash Airlines.

## U.S. Comment:

Page 326, Section 1.17.3.11 Flash Airlines program for training and checking pilots in the field of CRM and human factors (as contained in the company training manual)

This section states:
No mandatory training was required by ECAR at the time of the accident. However, CRM course is outlined in Flash Airline Training Manual 4.10

Suggest that the report explain whether the presence of an approved training module in the carrier's training manual meant that the company was obligated to provide the training to its pilots. Also suggest that the report explain why the ECAA's January 2003 audit of Flash Airlines would cite a lack of CRM training at Flash Airlines as an operational shortcoming when such training was not required in Egypt.

## U.S. Comment:

Page 326, Section 1.17.3.12 Flash Airlines pilots procedures for training and checking pilots on spatial disorientation countermeasures and upset recovery

This section states:

Spatial Disorientation training is not a requirement by Civil Aviation Authorities. However, some literature about this subject is included in Flash Airline Training Manual.

Relevant material contained in the Flash Airlines Manuals should be referenced, summarized, and inserted in this section.
U.S. Comment:

Page 327, Section 1.17.3.20 Previous violations, fines, or bans levied foreign aviation regulatory agencies

This section states:
None identified.
Information should be added to the report acknowledging the Flash Airlines violations documented by the Swiss government. In particular, the following details are known and should be added to the final report.

The Swiss FOCA conducted two Safety Assessment of Foreign Aircraft (SAFA) ramp inspections on Flash Airlines B-737 aircraft in 2002. Aircraft SU-ZCD was inspected on April 27, 2002, and SU-ZCF (the accident aircraft) was inspected on October 11, 2002. Egyptian authorities were informed by FOCA in writing of the results of both inspections. The inspections revealed numerous and significant safety-related deficiencies. According to FOCA, a ban was issued on further Flash Airlines flights to Switzerland effective October 17, 2002, because of the similarities of the inspection findings on the two aircraft and the lack of appropriate response by the airline to the safety issues.

## MCA Response:

Reviewing this report indicated that the ban was due to a conflict on financial issues and no relevant safety issues were mentioned.
U.S. Comment:

Page 327-333, Section 1.17.3.22 Airline Simulator program contract with RAM, ECAA letter of approval

This section contains several pages concerning approval of a Royal Air Maroc Boeing 737-500 simulator for use by EgyptAir, dated September 2003.

The report should clarify how this approval applied to Flash Airlines' training program and address the basis for the captain's apparent training on the simulator in April/May 2003 before the September 2003 approval of the simulator.
U.S. Comment:

Page 334, Section 1.17.3.23 Simulator used by Flash Airlines at RAM

The statement "pending Boeing response" should be deleted. The MCA asked Boeing for help in determining what differences existed between the RAM simulator used for the Flash Airlines training and the accident aircraft. Boeing forwarded a request for information to RAM and relayed their answer to the MCA on 1 Aug 2005.

MCA Response:
Adopted

This section should also include information about differences in the functioning of the Royal Air Maroc simulator and the accident airplane, such as differences in the sensitivity to direction of turn on the MCP heading knob.

## U.S. Comment:

Page 334, Section 1.17.3.24 Flash Airlines procedures regarding which pilot (PF or PNF) engages the autopilot, Boeing recommended practice

This section states:
No written procedure was found in Flash Airline FOM regarding this issue. Boeing procedures and common practices are for PF to connect the autopilot.

This section should note the Flash Air chief pilot's statements that it was company policy for the PNF to engage the autopilot, and information should be provided to explain why the procedure is contrary to Boeing procedures. This section should also note that the page of the Flash Airlines Flight Operations Manual dealing with this subject was missing.

## U.S. Comment:

Page 335, Section 1.17.3.25 Additional information regarding dispatch from SSH

This section states:

B- Extension of the outbound legs before beginning the turn
Interviewing Flash Airlines chief pilot: Flash Airlines chief pilot stated that during the departure from SSH , Flash Airline pilots might extend the circuit as the situations need whether day or night departures (departure over water is mandatory)

Actual pattern flown depends on airplane performance (weight, OAT, etc). Most airplanes widen the pattern to gain additional altitude as a pilot technique. VOR crossing altitude restriction is shown on charts. This information should be added to Operations Group Notes.

It is suggested that the report identify the crossing altitude and the charts that display the altitude crossing restriction for the SHM VOR that is referenced here.

The report should also note conflicting evidence on the prescribed crossing altitude. The Director of Radar Airports, National Air Navigation Service Company, told investigators that the minimum SHM VOR crossing altitude for ATC purposes was 4,000 feet, but pilots prefer to cross it above 10,000 feet. FDR data from previous flights of the accident airplane showed a departure from SSH requiring a turn to cross back over the VOR where no widening of the turn was evident, and the VOR was crossed below 7,000 feet MSL.

## U.S. Comment:

Page 338,1.18. Additional Information

Page 10 of 40

The section on this page titled, "Meeting with Captain Khedr's wife 24/10/2004" states, in part:

In the year 1999 he was awarded a prize when he landed in a difficult weather in Sarayevo.

Suggest that this information be clarified. It appears to conflict with the footnote on Page 142, Section 1.13.1, Egyptian Air Force - Medical Board Report, which states:

During the time from 1997 to 1999 the Captain held an administnve [sic] post (Chief of Staff of an Air force base) with no flying duties.

## MCA Response:

## Corrected

U.S. Comment:

Page 354, Section 7.3 Last PDC Carried out for the Accident Flight
See comments provided for p. 120, Section 1.6.6.3

## U.S. Comment:

Page 356:

This table of information should be titled, since it is unclear what it refers to.

## MCA Response:

## Adopted

## U.S. Comment:

Page 621, Exhibit C, Cockpit Voice Recorder (CVR), Group Factual Report

The "tsk tsk" vocalization attributed to the first officer (just before his statement "Overbank overbank overbank" that began at 02:44:48) should be added to the transcript and also evaluated in the analysis section of the report. The "tsk tsk" was confirmed and discussed during a meeting on August 22, 2005 held at MCA headquarters.

## MCA Response:

## Adopted

## ANALYSIS

## U.S. Comment:

## Page 698, Section 2.1 Analysis Overview

It is suggested that this section begin with a discussion of the analysis methodology and proceed to explain how the various group activities supported that methodology.

## MCA Response:

## Adopted

Page 699, Section 2.1, Analysis of Airplane systems behavior:

This section states that "several parameters had invalid data."
Control wheel position data was one of the anomalous parameters; however, these data were available from the M-cab data (see comment for $p$. 701). The remaining invalid data did not inhibit the investigation. The report should be modified to reflect both of these points.

Page 11 of 40

## MCA Response:

## Adopted

## U.S. Comment:

Page 699, Section 2.1 Analysis Overview
Under the bulleted item titled "Anaysis [sic] of the Main Events," the draft final report states that the investigative team categorized the main events as being directly related to the accident, not directly related to the accident, or those that might be considered as normal during flight. The U.S. and French teams did not participate in such an effort, nor does it appear that the draft final report includes any such reference.

MCA Response:

## Adopted

## U.S. Comment:

Page 700, Section 2.1 Analysis Overview
This section states, in part:
Two studies have been developed by the whole investigation tean [sic] jointly addressing both the:

- Systems analysis (fault tree)
- Crew behavior

The report should make clear that some of the material dealing with crew behavior in the analysis section was independently developed by the MCA and was not endorsed by the multi-national team.

MCA Response:
MCA was not able to identify any material independently developed and no such comment was presented by the French BEA
U.S. Comment:

Page 700, Section 2.1 Analysis Overview
This section states, in part:
See section "2.6 Crew Behavior", Thread Overview Updates Cairo 26-Aug-05, Flash Air CBS Sub-group Comments (24 August 2005)"

If the CBS working group comments are to be included directly in the report, the final version of these comments, dated August 25, 2005 should be included, rather than the preliminary, incomplete August 24, 2005, version that is included here.

MCA Response:

## Adopted

U.S. Comment:

Page 701, Section 2.2.1 General
This section states:
Several parameters were recorded in the FDR (related to the aircraft performance including):

- The movements of the pilot's controls:
- Control column
- Control wheel position (FDR data is not reliable)

While it is true that the control wheel data are not accurate as recorded on the FDR, the report should note that accurate control wheel data for the accident flight were available from the M-cab data and also from an NTSB study that involved application of corrections to match control wheel and aileron data. The M-cab data were the wheel positions required to match the roll angles and roll rates recorded on the FDR. As such, it
is a match that includes the control system model and the airplane aerodynamic model. Control wheel values developed by the NTSB study show good correlation with the Mcab data; the study also provides a likely explanation for the control wheel sensor fault.

Based on this information, the report should reflect the availability of the control wheel data.

## U.S. Comment:

## Page 710, Section 2.2.3, Conclusion (Sensitivity analysis):

Altitude was not one of the primary parameters matched for the M-cab simulations; rather, it is the result of the simulation attempting to match pitch attitude and vertical acceleration. Very small differences in column command would result in a more exact match of altitude, at the expense of matching pitch attitude.

## MCA Response:

## Adopted

## U.S. Comment:

## Page 716, Section 2.3.3 Flight Controls:

The first bulleted item states that the parameter for slat \#1 was unreliable (showed mid extend position).

The FDR data indicate that one of the slat indication lights was illuminated for the entire 25 hours of the FDR recording, and this light may have been the subject of the discussion on the CVR at 02:30:21. However, there is no record that this fault was documented in the airplane technical log. Although minimum equipment list (MEL) restrictions permit operation of the airplane with this fault present, there are operational restrictions on airspeed. These restrictions were violated on all 13 flights recorded on the FDR.

MCA Response:
No factual data about the slat indication lights is available
U.S. Comment:

Page 716, Section 2.3.3 Flight Controls:
The fourth bulleted item states:
Because the spoiler surface positions are not recorded in the FDR, any possible abnormality with the spoiler surfaces data can not be shown by the FDR.

Although flight and ground spoiler positions are not recorded on the FDR, the flight path
of the airplane is recorded. As the report correctly concludes, the motion of the airplane is consistent with the motion of the recorded control surfaces. Therefore, it can be concluded that no additional anomalous aerodynamic influences (e.g., spoiler abnormality) existed.

## MCA Response:

See Analysis chapter, section 6.3.5 Spoiler Fault

## U.S. Comment:

Page 716, Section 2.3.3 Flight Controls:

The last bulleted item states:
A full analysis of the aircraft lateral control system has been done (refer to appendix 2-1 lateral control analysis). All the hypothetical failures in the
system have been comprehensively studied. All the scenarios resulting from each individual failure (or combination of particular failures) were checked against the accident scenario. Most of the hypothetical failures scenarios were ruled out because of there inconsistency with the accident scenario. The remaining hypothetical failures scenarios showed consistency with the accident scenario. These hypothetical failures scenarios are as follows:

The remaining hypothetical scenarios were further examined because they could not be fully excluded based on a review of FDR data. There is no evidence to support a statement that the remaining hypothetical scenarios "showed consistency with the accident scenario." Consideration of the full investigative data did not support these scenarios.

As these statements highlight, the draft final report appears to have applied different standards to airplane issues versus operational issues. In most cases, the report considers airplane issues as possibly causal unless conclusive opposing evidence exists. Contrarily, operational issues are not considered causal (and in some cases not at all) unless proven to exist and influence the outcome of the accident.

## U.S. Comment:

Page 753, 2.5.5.1 Conditions which could lead to this event

This section states:
Although the rudder surface movement can contribute to this event, the rudder position as shown by the FDR at this interval of time was very small. The finding of having the rudder related to this event can only be accepted if consideration is given to the data received from Boeing in response to operator reports of abnormal flight control behavior related to rudder trim position and Boeing's interpretation of rudder trim effect on lateral control as being a possible cause of airplane rolling back to wings level and slow turn towards right due to the out of trim condition See Appendix 2-2 Studies of other airplane incidents relevant to autoflight systems. Case II "Autopilot Overbank

During the investigation by the multinational investigation, the rudder was ruled out as a possible contributor to the accident. In fact, the draft final report includes scenario tree pages showing the rudder ruled out (e.g., page 759 of draft final report). The rationale provided here and attributed to Boeing is misleading.

The event referred to in this section occurred on a different 737. The operator reported an autopilot overbank and provided the FDR data to Boeing for analysis. The FDR data indicate that the airplane experienced an overbank while attempting to engage the autopilot in an out-of-trim condition due to a rudder deflection of approximately 3 degrees. For more information on this event, see comments regarding page 980 of the draft final report.

Page 14 of 40

In the Flash Airlines case, the FDR data shows that both the rudder and rudder pedals were very nearly zero, a fact that is confirmed by the simulation analysis, which shows that the airplane's path is consistent with the recorded position of the control surfaces (including the rudder). This event is not relevant to the Flash Airlines accident.

The earlier conclusion that the rudder can be ruled out is correct and should be reflected in the final report.

## MCA Response:

Adopted
U.S. Comment:

Page 756, Section 2.5.5.3 Roll Left and beginning of Left Turn possible causes
This section states, in part:
The aircraft remained near heading 140 for 9 seconds. Roll rate decreases as aircraft nears 140.

This section should make it clear that the trend in roll rate continued, with some brief oscillations, as the airplane slowly rolled from left to right. Although the airplane's heading briefly remained near 140 degrees as the airplane passed through a wings-level flight attitude, the airplane's bank angle did not stabilize.

Page 772, Section 2.5.6 Pitch up and airspeed decay

This page states:
The possible conditions which might lead to this event are shown in the following:

1. Pilot Wanted to Gain Altitude Quicker (Intended Maneuver)

This probability may be supported by the fact that the airplane should intercept the VOR radial at a minimum of $11,000 \mathrm{ft}$
2. Pilot Following Erroneous FD (intended)

There are not enough data to rule in or rule out this probability
3. Relaxation of Control in Out of Trim Condition (Unintended Maneuver)

The results from the M-CAB tests match with FDR
4. Autopilot Fault (Unintended Maneuver)

This condition might be ruled out. This event started prior to AP
Engagement (based on FDR data)
5. Stab Trim Fault (Unintended Maneuver)

This condition might be ruled out. Based on FDR data, the stabilizer did not show abnormal behavior throughout the flight.
6. Pilot pulling on the control column (unintentional)

Conclusion:
With the exclusion of the ruled out (conditions 4 and 5), the investigation could
not determine a higher possibility to any of the remaining conditions (conditions $1,2,3$ and 6 ) based on the given data.

Page 15 of 40

```
In all cases, this event does not have direct relation to the accident
```

The following information and suggested changes are provided:

For condition 1, it is suggested that the word "probability" be changed to "possibility." It is not reasonable to intentionally pitch up the airplane and allow airspeed to decay below flaps-up maneuvering speed to gain altitude. In addition, the right bank began at about the same time as pitch reached its maximum value. The right bank was clearly inconsistent with the flight crew's departure clearance. This suggests that the captain was not adequately monitoring pitch or bank indications. In addition, the existence of a published altitude crossing restriction over the SHM VOR has not been well documented in the report.

For condition 2, the evidence indicates that the autopilot's automatic transition from command mode to CWS/R, which occurred during the time of pitch up and airspeed decay, happened because the captain was not closely following roll commands on the flight director. This conflicts with the possibility that the captain was closely following an erroneous flight director.

A seventh possible explanation for the pitch up and airspeed decay should be added in this section. This possibility, discussed during the August 2005 meeting of operational factors investigators and crew behavior subcommittee members and included in the August 25, 2005 CBS group comments, was that the captain may have become distracted from his primary flight control task. This bullet should be combined with bullets 3 and 6 , which would both be consistent with the captain's distraction.

With respect to the concluding statements, it should be acknowledged that the conclusion stated here was not agreed to by the multinational team. The available evidence best supports a conclusion that the pilot became distracted from monitoring aircraft attitude information.

## U.S. Comment:

Page 782, 2.5.7.2.2, The conditions leading to the event of engaging the autopilot are presented in the following:

The statements under bullets 1,2 , and 3 should state that the Boeing procedure is for the "pilot flying" to push the CMD button, not the "captain."

MCA Response:
Corrected
Page 785, Figure 2.5.7.4 Autopilot Engage Attempt with Time CVR Data
This figure contains a notation attributing the CVR statement "Not yet" to the observer. However, this statement was attributed to the captain in the final version of the CVR transcript

The attribution of this statement in the figure should be made consistent with the final
version of the CVR transcript.
Page 16 of 40

MCA Response:
Corrected

## U.S. Comment:

Page 794, 2.5.9 Aileron move in direction of right roll
A. Rudder surface movement:

This portion of the scenario tree is examining possibilities for aileron motion. Rudder motion does not cause aileron motion. The investigation previously ruled out the rudder (ref page 796 of draft final report), and the final report should reflect so.

MCA Response:
Adopted

## U.S. Comment:

Page 794, 2.5.9 Aileron move in direction of right roll
The draft final report indicates that a slat asymmetry was evaluated in the M-cab.
Slat failure analysis was not done in the M-cab. The final report should note instead that the simulations were conducted on computer workstations.

## MCA Response:

Adopted
U.S. Comment:
p. 795 , Conclusion

The conclusion at the bottom of the page states:
The investigation could not determine a higher possibility to any of the above findings (lateral system fault, pilot input) based on the given data.

There is no evidence of a lateral system fault, and it is suggested that the conclusion on this page can only be attributed to pilot input.

Page 803, Section 2.5.10 Autopilot Disengagement indications on the FDR and CVR
The sixth bullet on this page should note that the increase in pitch and the decay in airspeed began prior to autopilot engagement.

Page 811, Section 2.5.10 Autopilot Disengagement indications on the FDR and CVR
The statement that "the sensed pressure is not recorded on the FDR" should be rephrased to avoid misperceptions that it erroneously did not record the data. It is suggested that the sentence read, "the FDR does not record data regarding the hydraulic pressure at the autopilot aileron hydraulic switch."

MCA Response:
Adopted
U.S. Comment:

Page 814, Section 2.5.10.2 Autopilot Disconnect Analysis (based on FDR and CVR available data):
see same comment as provided for p. 785
MCA Response:
Adopted
U.S. Comment:

Page 815, Section 2.5.10.3 Probable conditions for autopilot disconnect:
1.1 Manual Disconnect

This section states:

> Warning length is consistent with "double click" typical of manual disconnects (within allowable warning duration tolerance)3. However, there is no disengagement callout by crew on CVR. In addition, the autopilot disconnect switches status on the control wheels horns are not recorded in the FDR.

This section should acknowledge the following information. The minimum time that the Mode Control Panel (MCP) will sound the autopilot disconnect warning when the autopilot disconnect button is pressed twice (i.e., "double click") is 1.5 seconds; the maximum time is 3.0 seconds, as provided in Honeywell's MCP Component Maintenance Manual document 22-11-84. Based on the CVR data, the autopilot disconnect warning lasted 2.136 seconds, which is within the allowable warning duration of 1.5 seconds (lower limit) and 3.0 seconds (upper limit).

Lack of conversation about autopilot disconnect on CVR could also suggest that the disconnect was expected and therefore a manual disconnect.

The statement at the end of the paragraph that "the autopilot disconnect switches status oh the control wheels horns are not recorded in the FDR" should be rephrased to avoid misperceptions that it erroneously did not record the data. It is suggested that the statement read "The FDR does not record data regarding the autopilot disconnect switch on the control columns."

## MCA Response:

- Boeing presentation (see 2.5.10.2) regarding autopilot function states that the duration of autopilot manual disconnect warning is less than 2 seconds
- Honeywell verbal information, states the duration of autopilot manual disconnect warning is max of 3 seconds
- Actual time of warning based on CVR is 2.136 seconds

Although requested, Honeywell did not supply the investigation team with any supporting evidence.
U.S. Comment:

Page 815, Section 2.5.10.3 Probable conditions for autopilot disconnect:
2. Case of Autopilot Does Not Engage

This case can be ruled out because the FDR shows that the autopilot did engage and the disconnect warning can be heard on the CVR.

MCA Response:
Adopted
U.S. Comment:

## U.S. Comment:

Page 815, Section 2.5.10.3 Probable conditions for autopilot disconnect:
The conclusion states:
The investigation could not determine a higher possibility to any of the above findings (Autopilot automatically disengaged or manually disengaged), based on the given data.

The data indicate that the autopilot disconnect was a manual disconnect initiated by the crew. From this point until the end of the flight, the FDR records that the autopilot remained disengaged.

## MCA Response:

This is not consistent with the outcome of the fault tree and the CVR information U.S. Comment:

Page 815, Section 2.5.10.3 Probable conditions for autopilot disconnect:
Footnote 3 on this page states "Verbal information from Honeywell but not documented"

The report should reflect that this information is provided in Honeywell's MCP Component Maintenance Manual document 22-11-84, revision 11, dated 15Jan2005, page 198.209

## U.S. Comment:

Page 820, Section 2.5.11.1 Conditions which could lead to this event
A. Rudder surface position"

This portion of the scenario tree is examining possibilities for aileron motion. Rudder motion does not cause aileron motion. The investigation previously ruled out the rudder (ref page 796 of draft final report).

MCA Response:
Adopted
U.S. Comment:

Page 821, Section 2.5.11 Airplane begins roll to right, Subsection 2.5.11.1 Conditions which could lead to this event

Section $F$ on this page states:

## F- Flight Crew Believes Autopilot is Engaged When it is not

Reference to FDR, CVR data and Crew Behavior studies, this condition could not be ruled out

It is suggested that this section be revised, since no evidence is provided to support this possibility. The CVR records that the autopilot disconnect warning sounded prior to the beginning of the right bank. On several later occasions, the captain requested that the autopilot be engaged.

MCA Response:
CVR clearly records F/O announcement "Autopilot in command" and later "No autopilot commander". This strongly supports the above statement "F"

## U.S. Comment:

Page 822, Section 2.2 Uncommanded (actuator faults only)
An uncommanded aileron control system input from an aileron autopilot flight control actuator requires three separate faults to be present simultaneously within the actuator: the arm solenoid commanded open, the detent solenoid commanded open, and the transfer valve spool jammed off center. Had any one of these three faults been present during the autopilot engage sequence, the autopilot would not have engaged. All three faults result in force applied to the wheel. This will only lead to airplane roll if the crew does not oppose the motion of the wheel. The FDR show aileron motion in both directions, which indicate that the crew was actively controlling the airplane. Therefore this condition can be ruled out.

## MCA Response:

Not adopted. See section 2.5.13
U.S. Comment:

Page 823, Section 3.4 Trim/Feel Unit Fault
This fault results in force being applied to the aileron control system, resulting in both of the control wheels and the ailerons moving to a uncommanded position corresponding to the force applied to the system. This will only lead to airplane roll if the crew does not oppose the motion of the control wheel.

Following the disengagement, and as the airplane continued to roll to the right, the FDR data indicates aileron deflection rates well in excess of the rates 0.6 degrees per second
that the aileron trim actuator can command. The aileron deflection rates indicated on the FDR can only be achieved through manual aileron control wheel inputs.

Furthermore, the investigation group evaluated the aileron trim runaway failure scenario in the Boeing Multipurpose Engineering Cab (M-cab) simulator. This scenario was demonstrated by investigators to be easily identified and controllable during the flight simulations, with only 15 pounds of control wheel force required to return and maintain the aileron control surfaces at the neutral position. Aileron motion in both directions indicates that the crew was actively controlling the airplane.

Based on this evidence, this condition can be ruled out.

## MCA Response:

Not adopted. See section 2.5.13

## U.S. Comment:

Page 848, Section 3.0 Rudder Surface Deflection

During the investigation by the multinational team, the rudder was ruled out as a possible contributor to the accident. The draft final report includes scenario tree pages showing the rudder ruled out (e.g., page 759). The rationale provided on p. 848 and attributed to Boeing is misleading.

The event referred to by this paragraph occurred on a different 737. The operator reported an autopilot overbank and provided the FDR data to Boeing for analysis. The FDR data indicate that the airplane experienced an overbank while attempting to engage the autopilot in an out-of-trim condition due to a rudder deflection of approximately 3 degrees. For more information on this event, see comments regarding page 980 of the draft final report.

In the Flash Airlines case, the FDR data shows that both the rudder and rudder pedals were very nearly zero, a fact that is confirmed by the simulation analysis, which shows that the airplane's path is consistent with the recorded position of the control surfaces (including the rudder). This event is not relevant to the Flash Airlines accident.

The earlier conclusion that the rudder can be ruled out is correct and should be reflected in the final report.

## MCA Response:

Adopted

## U.S. Comment:

## Page 850, Section 6.1.1.2 Following Erroneous EADI

The section on this page titled "6.1.1.2.2 Alternate Instruments Not Cross-Checked" section states:

From the Crew Behavior Subcommittee study, this condition could be ruled out. This section should be revised. There was no joint CBS study conclusion that the flight crew cross-checked their instruments.

MCA Response:
Adopted

## U.S. Comment:

Page 850, Section 6.1.1.4 Pilot Loses Situational Awareness

The subsection on this page tilled "6.1.1.4.1 Captain experiences SD Type II" states:

Page 20 of 40

See Section 2.6.1 Crew Behavior Subcommittee, this condition could not be ruled out

It should be further stated here that loss of situational awareness and spatial disorientation for the captain is consistent with available data and with CBS group comments from 25 August 2005.
U.S. Comment:

Page 852, Section 6.2.2.3.1.1
Both Solenoids and Transfer Valve Jammed (Autopilot actuator, both Solenoids and Transfer Valve Jammed (Actuator Hardover without Force Limiter 17 to 20 lb Force)

The report states that "the cause of these failures cannot be conclusively identified."
However, it is known that these faults were not present during the autopilot engage sequence. This hypothetical scenario would require that the faults occur after the time the autopilot was engaged. Furthermore, it would result in relatively small forces applied to the wheel. The M-Cab evaluations found that this condition is easily controllable by a crew aware of their attitude. It would only lead to airplane roll (and overbank) if the crew does not oppose the motion of the wheel. Aileron motions recorded on the FDR indicates the crew was actively controlling the airplane.

Based on this evidence, this condition can be ruled out.

## MCA Response:

Refer to the analysis in 6.2.2.3., which shows close consistency with the existing data
U.S. Comment:

Page 854

This page states, in part:
Therefore, it could be concluded that this hypothetical condition shows close consistency with the event. This condition is also consistent with the possibility of recovering the airplane when appropriate quantity of input is applied timely on the airplane ( M - Cab tests).
(See also section 2.6 Crew Behavior)
This condition could not be ruled out

These conclusions should be clarified. It is unclear which parts of section 2.6 support this conclusion. The CBS group concluded that the appropriate action to take at high angles of bank, prior to recovery, was to apply full opposing aileron. The hypothetical fault described in this section would not have prevented the crew from doing this. This scenario was demonstrated to be easily controllable in the M-Cab by pilots who were aware of their attitude. This hypothetical fault by itself cannot explain the continued right roll to overbank.

MCA Response:
This scenario was demonstrated to be easily controllable by pilots who were aware of the hypothetical fault and identified the required corrective action.
U.S. Comment:

Page 863, Section 6.3.4 . 2 Aileron Trim Runaway to 60 deg.

Page 21 of 40

A bullet under the heading of this section titled, "This condition could not be ruled out based on the following" states:

- Consistent with Crew Behavior study

This statement should be clarified or further supported. This fault was not explicitly addressed in any of the crew behavior subcommittee documentation.

In addition, it should be noted that all pilots were able to easily control this fault in the M-Cab. Assuming this fault existed, the captain would have been able to move the ailerons towards neutral with approx 20 lbs of force. There is no explanation given here as to why the captain could not have applied the small additional force to roll back to wings level. During the recovery attempt, the FDR data shows the crew was able to achieve high roll rates towards wings level. Even in the presence of this assumed fault, the crew inputs cannot be explained if the captain was aware of the airplane attitude, suggesting the presence of spatial disorientation.

## U.S. Comment:

Page 888, Section 6.3.5.3.1 Scenario 10 - Spoiler wing cable jam
This section stales:

This condition could not be ruled out, based on the following:
The results obtained from the M-Cab test show a very close consistency with the FDR data which may explain this event. The estimated aileron wheel forces needed to move the wheel to correct for the right turn tendency is $\sim 50 \mathrm{lbs}$. The timing and length of the Captain speeches through this event does not provide sufficient information to verify the effect of this force on the speech tone

This conclusion should be revised.
If this fault had existed, the captain would have been able to move the ailerons towards neutral with approximately 50 lbs of force. It is reasonable to expect the captain would have been able to apply the additional force necessary to roll back to wings level. The M-Cab work demonstrated that all participants were able to apply in excess of 80 lbs to the wheel to control the airplane. This scenario is not consistent with the M-Cab results. The M-Cab results demonstrated that participants could apply in excess of 80 lbs to the wheel to control the airplane.

Furthermore, at the time this fault is postulated, the airplane was already banked in excess of 25 degrees to the right. No explanation is given to explain how the airplane reached 25 degrees right bank.

The last line of this section states:

Crew behavior study shows consistency

Page 22 of 40

This statement should be removed. The CBS group documentation does not address this scenario, and it does not reflect discussions by the CBS group.

## MCA Response:

This scenario was demonstrated to be easily controllable by pilots who were aware of the hypothetical fault and identified the required corrective action when the required additional force was 50 lbs and not the case of 80 lbs .

## U.S. Comment:

Page 894, 6.3.5.3.2 Scenario IOa - F/O wheel jam (F/0 wheel jam) offset of the neutral position at time 92450 (maximum wheel deflection). and clears at 92472

The section states, in part:

- All the parameters obtained from the M-Cab test with the fault inserted show very close consistency with the accident flight FDR data

This conclusion should be revised. This scenario is not consistent with M-Cab results. The M-Cab results demonstrated that participants could apply force in excess of 80 Ibs to the wheel to control the airplane. Furthermore, at the time this fault is postulated to have occurred, the airplane was already banked in excess of 25 degrees to the right. No explanation is given to explain how the airplane reached 25 degrees right bank.

The section states, in part:
This condition could not be ruled out, based on the following:
The results obtained from the M-Cab test show a very close consistency with the FDR data which may explain this event. The estimated aileron wheel forces needed to move the wheel to correct for the right turn tendency is $\sim 50 \mathrm{lbs}$ or slightly higher. The timing and length of the Captain speeches through this event does not provide sufficient information to verify the effect of this force on the speech tone

This conclusion should be revised. Assuming this fault existed, the implication is that the captain was able to move the ailerons towards neutral with approx 50 lbs of force. It is therefore reasonable to expect the captain would have applied the additional force necessary to roll the airplane back to wings level. The M-Cab work demonstrated that all participants were able to apply in excess of 80 lbs to the wheel to control the airplane.

The last line of this section states:
Crew behavior study shows consistency
This statement should be deleted. The CBS group documentation does not address this scenario, and it does not reflect discussions by the CBS group.

## MCA Response:

This scenario was demonstrated to be easily controllable by pilots who were aware of the hypothetical fault and identified the required corrective action when the required additional force was 50 lbs and not the case of 80 lbs .
U.S. Comment:

Page 894, 2.5.13 Right roll continues to overbank with ailerons activities

A conclusion section should be added to summarize the information regarding the right bank continuing to overbank. The evidence suggests that captain's spatial disorientation was the most likely cause for the overbank.

## U.S. Comment:

Page 901, Figure, 13.0 Right Roll Continues to Overbank with Aileron Activity
According to Rockwell Collins, the EFIS Failure Mode Effect Analysis (FMEA) does not list any potential failure modes which would result in the failure indication of "Offset Airplane Reference." This failure mode has never been reported in the operational history of EFIS-equipped Boeing 737, 757 and 767 aircraft.

The report should be amended to account for this information, and the report should delete the statement, "Boeing to ask Rockwell Collins if this fault can actually occur."

## MCA Response:

No official information from Boeing or Rockwell Collins has been received (fault tree page 7 of 22)

## U.S. Comment:

Page 919, 2.5.14 Flight crew CVR autopilot announcements
This section states, in part:
Flight crew CVR autopilot announcements might be explained by the following:

1. Requests for Autopilot Engagement

This scenario is consistent with expected normal airplane operation. If the Captain asked for autopilot and the F/O pressed the CMD button, the interlocks would not be satisfied because of forces on the control wheel. In this case, the button push is not recorded as an autopilot engagement on the FDR. (Done on M-Cab)

It is suggested that this section further note that the command "Autopilot" is not only standard terminology used to request the autopilot, but was used by the captain earlier in the flight to request the autopilot. Furthermore, according to the FDR, there were no indications on the flight deck that the autopilot was already engaged when the captain began calling for the autopilot during this period in the flight.

Engaging the autopilot may be an appropriate response if the pilot was not aware of the true attitude of the airplane.

## MCA Response:

No evidence supporting this statement.

This section also states, in part:

## 4. Announcement of Perceived Autopilot Behavior

The report should specify which flight crew statements could be explained by this item. There is no reason to believe the captain and the first officer's statements during this period were announcements of perceived autopilot behavior. Indications on the flight deck were that the autopilot was off at this time. Flight crew statements are consistent

Page 24 of 40
with attempts to engage the autopilot. The data do not support this explanation of the flight crew's autopilot announcements.
hMCA Response:
CVR clearly records F/O announcement "Autopilot in command" and later "No autopilot commander".

This section also states, in part:
5. Requests for Autopilot Disengagement This condition requires perception on the part of the Captain that the autopilot is engaged

It is suggested that evidence conflicting with this explanation be included here. This explanation is highly unlikely because "Autopilot" is the standard terminology used to request that the autopilot be engaged, and was used by the captain earlier in the flight to request the autopilot. In addition, it is unlikely that the PF would repeatedly request that the PNF disconnect the autopilot, as each pilot has a disconnect button on their own control wheel. Furthermore, FDR data indicate that there were no indications in the cockpit during this time that the autopilot was engaged.

## MCA Response:

CVR clearly records F/O announcement "Autopilot in command" and later "No autopilot commander".

This section also states, in part:
The investigation could not determine a higher possibility to any of the above conditions based on the given data.

It is suggested that this conclusion be revised. It pre-supposes that items 1-5 are mutually exclusive, and they are not. Items 1,4 , and 5 all refer to the captain's pronouncements of "Autopilot" and they are mutually exclusive explanations for these announcements. Items 2 and 3 refer to different announcements.

The meaning of the flight crew's statements regarding the autopilot during this period are unambiguous. The captain's "autopilot" statements are consistent with requests for autopilot engagement. The first officer's statement, "Autopilot in command" is consistent with a rote response following a press of the command button. The first officer's statement, "No autopilot commander" is consistent with an attempt to communicate to the captain that the attempt to engage the autopilot was unsuccessful.

## MCA Response:

MCA does not agree with this statement as it is highly speculative and not supported by factual information.
p. 962,1- CASE of "AUTOPILOT REPORT OF EXCESSIVE RATE OF DESCENT"
1 - BOEING REPLY, EXCESSIVE RATE OF DESCENT
Discussion of this case includes correspondence between Boeing and a different operator concerning a report of excessive rate of descent while using autopilot A. The fault was the result of an intermittent column cutout switch that prevented the autopilot from commanding the required stabilizer trim. The autopilot lacked sufficient authority to overcome the out-of-trim condition.

In the Flash Airlines case, the FDR data shows that the autopilot was engaged for only one interval of 3-4 seconds. There is no evidence of an excessive descent rate during
those 3-4 seconds, nor is there any evidence of insufficient autopilot authority. Therefore, this event is not relevant to the Flash Airlines accident.

The details and correspondence of the event involving the excessive rate of descent have been previously provided but are provided again for the MCA's reference.
-Event Summary-
On 21 Oct 04, the operator reported that one of their 737-500 airplanes had experienced an autopilot anomaly described as follows:

Pilot Report - After airborne and approaching flight level 120, "ALT ACQUIRE" comes on the FMA then the A/C descended with V/S \}800ft/min to flight level 116 (with A/P A engaged only).

The operator further reported that the fault had repeated on a number of occasions (always with autopilot A) and maintenance actions that had been taken in an attempt to correct the fault and requested assistance from Boeing.

From 21 Oct to 6 Dec, Boeing and the operator exchanged troubleshooting recommendations and test results. On 1 Dec , the operator requested on-site engineering support to result the recurring fault. A Boeing engineer traveled to Cairo to assist the operator. During the on-site work, an intermittent fault was found in the column cutout switch for autopilot A. It is suspected, that the high resistance of the SI closed contacts resulted in the FCC intermittently detecting the SI as open when the contacts were actually closed. This condition would inhibit the trim up command output from the $A$ channel autopilot. This fault condition correlates to the FDR data that showed the A channel would not trim up when expected resulting in a loss of elevator authority and subsequent increase in descent speed. This fault condition also correlates to the report that proper trim up returned once the B channel Autopilot was engaged.

The operator replaced the faulty switch. Booing has received no further reports of this condition.

## U.S. Comment:

## p. 980, II- CASE of AUTOPILOT OVERBANK

1- Case of Overbank Follow up:
Discussion of this case includes correspondence between Boeing and a different operator concerning a reported autopilot overbank event that resulted from attempting to engage the autopilot with the airplane out-of-trim due to non-zero rudder deflection.

In the Flash Airlines case, the FDR data shows that both the rudder and rudder pedals were very nearly zero, a fact that is confirmed by the simulation analysis that shows that the airplane's path is consistent with the recorded position of the control surfaces (including the rudder). This event is not relevant to the Flash Airlines accident.

Page 26 of 40

The details and correspondence of this event have been previously provided but are provided again for the MCA's reference.

## -Event Summary-

On 27 Mar 2005, the operator reported that one of their 737-500 airplanes had experienced an autopilot anomaly described as follows:

During departure with LNAV engaged, AP "B" selected, the AP "B" engaged then disengaged. After satisfying F/D, again AP selected. At UTC 20:14 the autopilot gave more than 35 degree bank angle and increased. A/P disconnected followed by F/D pitch bar out of view, F/D switches recycled. Flap retraction and leveled, AP selected and operation normal.
The operator provided the FDR data for analysis.

On 28 Mar 2005, Boeing provided the following analysis to the operator.

The FDR data indicate that the airplane experienced an overbank during an attempted autopilot engage because the airplane was in a small nose-left sideslip as the result of rudder pedal being deflected to approximately 1.5 degrees nose left. The reasons for this are unknown and cannot be determined from the FDR data, but the trim likely arose either from crew trim inputs during the takeoff roll (possibly inadvertent) or from something sticking in the rudder feel and centering unit. The simulation confirms that the sideslip resulting from the pedal input would have required approximately 25 degrees of right control wheel deflection to maintain wings level flight, as indicated by the FDR data. During each attempt to engage the "B" autopilot, the wheel was released to neutral and the airplane rolled at between 2 and $2.5 \mathrm{deg} / \mathrm{sec}$ as a result of the sideslip-induced roll.

Boeing has received no further reports of this condition.
U.S. Comment:

Page 992, 2.6.1 Flash Airlines Flight 604 Investigation Crew Behavior Subcommittee

This section of the report states, in part:
Examination of evidence pertaining to specific phases of the accident

1. From the roll input that initiated a right roll from wings level (from around time 104) through the statement by the Capt, "how turning right", (around time 02:44:37), the committee agrees that the above three conditions are met, and it is therefore possible that the Capt was experiencing type I Spatial Disorientation.
2. From the statement by the Capt, "How turning right", to the beginning of sustained left roll (around time 158), evidence for orientation or disorientation is inconclusive given currently available data.

Page 27 of 40
3. After the first officer says "no autopilot commander" and sustained left control inputs begin the committee agrees that there is evidence that someone was properly oriented and manual recovery of the aircraft was initiated.
4. The committee agrees that there is no evidence suggesting spatial disorientation on the part of the first officer.
5. The committee agrees that the flight crew exhibited some positive CRMrelated behaviors during the flight; however, further analysis in this area is required.

## Closing Comments

This is a preliminary report. More work is needed to comprehensively address all human factors issues relevant to this accident, as needed.

This page contains an excerpt of the minutes of the first meeting of the Crew Behavior Subcommittee, held in August 2004. These preliminary investigative materials should not be included in the report. The crew behavior subcommittee did not adopt these points as its final conclusions during the final meeting of the group in August 2005. In fact, the full range of investigative evidence available by August 2005 did not support preliminary conclusions 2 and 5.

Point 2, which states that evidence for spatial disorientation after the captain's statement "how turning right" was inconclusive, was a preliminary conclusion pending simulation work and the development of systems group conclusions about the functioning of aircraft systems. Evidence for the captain's spatial disorientation was considered inconclusive in August 2004, because Egyptian officials insisted that there had been a systems malfunction that would account for control surface movements after the captain's statement, "how turning right." However, subsequent investigative work ruled out the likelihood of a lateral control systems malfunction. Therefore, type II spatial disorientation is the most likely explanation for the captain's continued inappropriate manual control inputs, and the evidence indicates that the captain's spatial disorientation persisted at least until the beginning of the attempted recovery maneuver.

Point 5 was superseded by later investigative work. During its August 2005 meeting, the crew behavior subcommittee identified a number of deficiencies in the CRM-related behaviors of the flight crew. These deficiencies should be discussed in the report.

MCA Response:
All crew behavior subcommittee work has been included in the report with no differentiation between preliminary and otherwise.

The report reflexes the interpretation of the Egyptian Investigation Team and specialized advisors.

This applies to all U.S. comments regarding Section 2.6
U.S. Comment:

Page 993, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior

Subcommittee August 2004

This section states, in part:
According to the meeting held on Aug. 23-26, 2004 and attended by representatives from NTSB, BEA and Boeing. The committee agreed that the Captain was possibly experiencing "Type I Spatial Disorientation" in the 1st stage of the accident.
In the 2nd stage the evidence of "Spatial Disorientation Type I" is inconclusive.

In the 3rd stage there is no evidence of this disorder.
The statements above are the MCA's interpretation of the August 2004 preliminary findings of the crew behavior subcommittee, which were developed based on the MCA's assertion that a lateral control system malfunction had occurred. The statements on this page were not jointly developed, nor endorsed by all members of the CBS group. The full range of evidence developed during the course of the investigation points to spatial disorientation as the most likely explanation for the captain's control inputs mid-way through the upset. The evidence suggests that the captain was experiencing type II spatial disorientation during this stage of the event.

It is suggested that the term "disorder" not be used to describe the occurrence of spatial disorientation in the aviation environment. Spatial disorientation is a normal human response to the accelerations of flight when accurate visual information about attitude is either not available or is not adequately monitored.

It is suggested that the remainder of section 2.6.2, pages 993-998, be labeled as work developed independently by the MCA.

## MCA Response:

## See MCA previous comment

## U.S. Comment:

Page 993, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

This section states, in part:
On 15 February, 2005 a message was received from NTSB including analysis of the Captain Behavior.

The scenarios included the word "Confusion "and not "Spatial disorientation type I"

It is suggested that excerpts from the NTSB message referred to here be included in this section of the report. The purpose of this reference is unclear.

## U.S. Comment:

Page 993-994, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The discussion of the term "confusion" on p. 993 should acknowledge that spatial disorientation can cause confusion about aircraft attitude.

The table on page 994 should be clearly labeled as work performed independently by the

MCA. The multinational CBS group did not jointly perform or endorse this material.
The table should also be revised. It appears to have been developed to provide criteria for distinguishing among four different psychological states or conditions. However, the labels confusion, spatial disorientation type I, distraction, and mistake are not mutually exclusive psychological states or behaviors. They are not adequately defined in this section, and no scientific research is referenced to support the attributes assigned to them.

## U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

This section states, in part:

## Captain:

We apply the above table to the circumstances of the accident. The highest probability is that the captain suffered from distraction accuracy during the 1st stage only.

The meaning of "distraction accuracy" should be clarified.
U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:
The captain was the 1st to attract attention of the rest of the crew that something wrong is happening in the airplane "see what the airplane is doing ".

The quote "See what the airplane is doing" should be modified so that it is consistent with the CVR transcript, which documents the captain's statement as "See what the aircraft did." The interpretation of the captain's statement should be modified as well. The captain's statement suggests surprise at aircraft behavior, but it does not provide evidence determining whether this aircraft behavior was normal or abnormal. This statement occurred soon after the flight crew attempted to engage the autopilot, and the autopilot transitioned to CWS-R mode. The transition to CWS-R mode occurred because the captain was not closely following flight director guidance at the time of autopilot engagement. Although this occurred in accordance with nominal system operation, it was an unusual occurrence that the captain may not have expected or understood, and it likely explains the captain's statement, "See what the airplane did."

MCA Response:

## Corrected

## U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:

This was shared by other crewmembers, as they assisted the captain in the same direction. Their observation and responses were centered on "right bank" and "autopilot".

The first sentence should be revised. The meaning of the statement "This was shared by other crewmembers" is unclear.

## U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:
Captain was alert with good concentration in the 2nd and 3rd stage as shown by his orders, responses and 3 appropriate actions taken (to the left):

- 1st action Lt input after words "How Right"
- 2nd action Lt input "OK come out"
- 3rd action Lt input "OK come out"

It should be acknowledged that captain could have been alert and concentrating but remained affected by type II spatial disorientation. Lack of alertness is not a prerequisite for spatial disorientation.

The statement, " 3 appropriate actions taken (to the left)" should be revised to acknowledge that during the 24 seconds between the captain's response, "What" and the beginning of appropriate control inputs consistent with an attempted recovery maneuver, only two control wheel inputs left of neutral were recorded, and these inputs lasted less than two seconds each. All other recorded inputs were right of neutral. Taken together, this evidence indicates that the captain's control wheel inputs during this period were predominantly to the right.

## U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:
During 1st stage (critical stage) there was signs indicating astonishment (How Right) also signs of Hesitation (turning right sir).

This statement should be revised so that the statements match the CVR transcript and that the person making each statement is clearly identified. Also, the statement that there were signs of "hesitation" with respect to the first officer's statement "turning right sir," should be better explained.

## U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

This section states, in part:
1st period (Pre-critical)
There were talks in between all crew members and between crew members and
A.T.C. and attendant. Answers and comments are immediate and correct pointing
to normal orientation and concentration. The mode and content of sentence show no evidence of disturbance of mood or intellectual functions. The conversations

Page 31 of 40
were calm and decisive with no evidence of anxiety or tension. There is no evidence of Euphoria or depressed mood.

This summary of flight crew communications should include information about CRM deficiencies discussed during the August 25, 2005, meeting of the crew behavior subcommittee.

## U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:
2nd period (Critical)
Starting by the phrase "Eddilo" (time 2:44:1) this was followed in few seconds by an important observation of the captain indicating that something is going wrong with the airplane.
This was followed by a 1-- period of hesitation, astonishment lasting for less than ten seconds.

This section should be revised. The "important observation of the captain indicating that something is going wrong with the airplane" referred to here appears to be the captain's statement "See what the aircraft did." As discussed earlier, this does not indicate that something was wrong with the airplane, as is implied here.

The captain's lack of speech for a number of seconds after his statement "See what the aircraft did" does not indicate that the captain was hesitating or was astonished. It simply indicates that he was not engaged in communication with the first officer. It is not possible to determine where his attention was focused during this time. However, the lack of control inputs that were needed to counteract the developing right bank suggests that the captain was distracted from monitoring attitude information during this time.

## U.S. Comment:

Page 995, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:
All crewmembers are anxious during this period of hesitation and astonishment ended by the captain saying "how turning right ".

This statement should be deleted. There is insufficient evidence to document the mood of the two pilots and the observer during the ten seconds preceding the captain's statement "how turning right."
U.S. Comment:

Page 996, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior

Subcommittee August 2004

Page 32 of 40

The section states, in part:
Both F.O. and extra crew 1 did not contradict the captain's orders or actions until the end of accident. This shows that in their estimation the captain was acting in the proper way.

The failure of the first officer to take more assertive action to reverse the direction of roll does not provide evidence that he believed the captain was acting properly. Rather, it indicates that he did not have the skills or did not feel adequately empowered to take assertive action. In fact, the first officer's "tsk, tsk" vocalization, confirmed during the August 2005 meeting of the crew behavior subcommittee meeting, was interpreted by some group members as a sign of frustration with the captain. This contradicts the assertion that the first officer believed the captain was acting in a proper way as he rolled the airplane into the overbank.

## U.S. Comment:

Page 996, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:
If they felt he is wrong they would have (at least) suggest any other action.
As the crew were in stress this logically abolishes the respect of seniority.
This statement is unsupported. Numerous accident investigations have documented the failure of junior crew members to challenge a captain's inappropriate actions. Moreover, past accidents have demonstrated that stress does not necessarily abolish deference to authority among junior flight crew members.

Page 996, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

The section states, in part:
If captain is acting wrongly they would have screamed loudly and aggressively there is no evidence of this (C.V.R.).

This statement should be revised because it is contradicted by evidence on the CVR. The first officer's voice became noticeably louder as the overbank grew more severe and the captain failed to correct it. However, the first officer did not escalate his assertiveness by providing direction, issuing commands, or taking timely control of the airplane. The investigation revealed that he had not been provided with CRM training, which could have provided him with better skills for intervening in this kind of situation.

Pages 997-998, Section 2.6.2 Flash Airlines Flight 604 Investigation, Crew Behavior Subcommittee August 2004

Page 33 of 40

The report should acknowledge that the fault tree diagrams on these pages were modified independently of the full investigative team.

## MCA Response:

All fault tree diagrams included in this report have been the outcome of work processed by Boeing through meeting in Cairo and email communication with no changes affected to it by any single party.
U.S. Comment:

Pages 1000-1006, Section 2.6.3 Flash air CBS Sub-group comments (24 August 2005)

These pages of the report should be removed and replaced with the final version of the CBS Sub-group comments completed on August 25, 2005. The version contained in this draft of the report was a preliminary document.

MCA Response:
Adopted
U.S. Comment:

## p. 1035, Flash Airlines 737 SU-ZCF Thread Diagram

The note at the bottom of the page states, "All possible scenarios being considered to explain the accident can be represented as a path from left to right through this diagram."

This comment highlights the need for a chronologically complete explanation for the accident flight, as agreed to by the investigative team. The possible causes by the draft final report do not satisfy this methodology.

## U.S. Comment:

p. 1038, 9.0 Aileron Motion (Right Roll)

The statement "Need to Revisit" under the title on this page should be resolved.
The following comments are provided regarding statements under the columns for "Pros" and "Cons" about the possible similarity of the aileron movements recorded on the FDR to that associated with autopilot behavior and also about the statements "(there was no consensus on this point)."

The aileron motions around the FDR time 92414 (while the autopilot was briefly engaged in CWS-R) was specifically examined by the investigative team to determine if the
aileron deflection resulted from a manual (pilot) input or was commanded by the aileron autopilot system. The analysis included comparison of the aileron deflection (magnitude and duration) with previous manual and autopilot movements of the ailerons. The results of the analysis indicate that the deflection of the ailerons around the FDR time of 92414 was consistent with manual input.

Furthermore, two computer simulations were conducted to analyze how the autopilot would command the ailerons. Neither of these simulations showed aileron motions that closely matched the aileron deflections at time 92414.

The Egyptian team did not agree with either of these points.
U.S. Comment:
p. 1042, 13.0 Overbank (2 of 2)

The four statements on this page that "MCA requests that simulation be redone at point on maximum wheel deflection" should be deleted. These simulations were performed and the results provided to the MCA.

Furthermore, the results of the simulations for these hypothetical scenarios showed that the ailerons can still be controlled via the captain's control wheel. High control wheel forces would be involved in moving the control wheel, and M-cab simulations for control wheel forces of this level showed that the effects on speech would be noticeable and audible on the CVR. The accident airplane's CVR contained no such effects.

## U.S. Comment:

Page 1044, Section 2.6.7 Thread Overview Updates Cairo 26-Aug-OS, Flash Air CBS Sub-group Comments (24 August 2005)

The section states, in part:
The study performed by a team of qualified Human Performance Specialists have come up with findings summerized [sic] as follows:

This statement needs to be clarified. It should identify which of the preceding pages contain the material referred to as the study performed by the human performance specialists.

The second bullet on this page states:

- There are conflicting signals in the following period of time (-17 seconds), it is unclear whether the captain remained in SD or was the crew unable to perceive the cause that was creating an upset condition until the time when the F/0 announced that there was no A/P in action.

This bullet should be revised to be consistent with the 25 Aug 2005 CBS comments, which were not included in the draft final report. These comments proposed that the captain was transitioning to type II spatial disorientation after his statement "How turning right." In light of the full range of evidence now available, which does not support the presence of a lateral control system malfunction, spatial disorientation is the most likely explanation for the captain's continued inappropriate control wheel inputs, which persisted for at least 17 seconds after that statement.

## U.S. Comment:

Page 1045, Section 3 Conclusion, Summary
The first item under "General Background" states that "the A/C was serviceable at take off and was operated within the approved limitations."

The lack of write-ups on the slat and TOGA anomalies, which resulted in operation of the aircraft outside MEL limitations, makes this statement questionable. However, neither of these two conditions appeared to have any effect on the accident sequence.
U.S. Comment:

Page 1045, Section 3 Conclusion

This section states, in part:

Page 35 of 40

The crew members held appropriate licenses and were qualified for this flight.
This conclusion should be revised to address questions regarding the crewmembers' training. As stated earlier in these comments, the investigation did not adequately document whether the captain had fulfilled all of the training requirements for his position, as required under Egyptian Civil Aviation Regulations. The MCA was unable to produce documentation verifying the captain's completion of the required number of hours of ground instruction and company indoctrination training. In addition, it is unclear whether the ECAA had approved Flash Airlines' use of the Royal Air Maroc simulator for the captain's flight training. Finally, neither pilot had received CRM training, as stipulated in Flash Airline's ECAA-approved training manual.

## MCA Response:

The Egyptian investigation team has reviewed all pertinent documentations with regard to pilot's training and qualification and is satisfied that the ECAA issued licenses are in accordance with local and ICAO requirements and all documents are included in this report.

## U.S. Comment:

Page 1045, Section 1.1, Simulation Procedure
Statements in this section improperly cast doubt on the availability of control wheel data. Although the control wheel data recorded on the FDR was erroneous, accurate control wheel data was available from the M-cab. This section should also note that the motion of the airplane is consistent with recorded motion of control surfaces.

This section also appears to cast doubt on the M-Cab tests. As previously commented, the simulations (including M-Cab) were demonstrated to accurately model the behavior of the airplane for the purposes of the investigation.

## U.S. Comment:

Page 1047, Section 2.2 Crew behavior
This section states:
Evidence of distraction possibly becoming spatial disorientation is observed from the time of start of right turn until the announcement of aircraft turning right, after which it is unclear whether the captain recovered or remained in the the [sic] state of spatial disorientation. After the call "No autopilot commander", the crew behavior appears normal.

As stated earlier in these comments, the full range of evidence collected during the investigation indicates that the captain remained spatially disoriented at least until the recovery attempt began. Because there is inadequate evidence to make a definitive conclusion regarding which crewmember initiated the attempted recovery maneuver, it is not possible to determine whether the captain had reacquired an accurate sense of spatial orientation by that time.

## U.S. Comment:

Page 1048, Section 3.5 Roll back towards wing level

This section states, in part:

The following conditions could not be ruled out:

Page 36 of 40

- Rudder surface position6 (Adopted)
- Pilot widening departure pattern (intentional control action)
- To level wings prior to engaging autopilot (intentionally)
- Pilot loses awareness of heading or bank (unintentional)
- Anomalies with the lateral control system

The investigation could not determine a higher possibility to any of the above findings based on the given data

As previously stated, the investigation ruled out any involvement by the rudder in the accident.

Although the second and third bullets could not be ruled out, the mostly likely cause is that the "pilot loses awareness of heading or bank."

It is suggested that a new section for "pitch up and airspeed decay" should follow this one and cite distraction as a likely reason for these deviations from target parameters.

## U.S. Comment:

Page 1049, section 3.9 Aileron move in direction of right roll.
This section states:

- Rudder surface position (See footnote \# 6) (Adopted)
- Pilot input
- Lateral system fault:

The investigation could not determine a higher possibility to any of the above findings based on the given data.

The rudder and rudder control system can be ruled out. During the multi-national investigative team's work, the rudder was ruled out as a possible contributor to the accident.

There is also no evidence of a lateral control system fault, and it should therefore be ruled out. The only remaining possibility for this section is "pilot input."

## U.S. Comment:

Page 1049, section 3.10, Autopilot Disengagement indications on the FDR and CVR.
This section states that the investigation could not determine a higher possibility to whether the autopilot was manually or automatically disengaged.

If the flight control computers (FCCs) detect an invalid input from any autopilot system sensor during the autopilot engagement sequence, the engagement sequence will stop and an automatic disconnect occurs. The minimum time for an automatic autopilot disconnect
is 3.695 seconds. It is known from analysis of the accident airplane's FDR data that the autopilot was engaged a maximum of 3.6 seconds, and most likely less than this.
Therefore, since the engagement time indicated on the FDR is less than the minimum
time required for an automatic autopilot disconnect, it can be concluded that the autopilot was manually disengaged.

## U.S. Comment:

Page 1049-1050, Section 3.11 Airplane begins roll to right
The investigative team has already ruled out the rudder and the rudder control system, and the report should reflect this point. There is also no evidence of an autopilot or lateral system fault, and they do not prevent controlling airplane to the desired flight path.

In addition, this section currently contains no conclusion. It should indicate which of the possible explanations is most likely. Manual pilot inputs resulting from the captain's unrecognized spatial disorientation best explain the airplane's entry into a right bank.

## U.S. Comment:

Page 1050, Section 3.13 Right roll continues to overbank with ailerons activities
The report states that the conditions listed in this section could not be ruled out and that the investigation could not determine a higher possibility to any of the conditions based on the given data.

The investigative team has already ruled out the rudder and an erroneous EADI, and the report should reflect these points.

Conditions related to an autopilot or lateral control system faults are not supported by the data. There is no evidence that these faults occurred, and they do not prevent controlling airplane to the desired flight path.

The captain's continued spatial disorientation is the most likely explanation for his continued inappropriate control wheel inputs during this period.

## U.S. Comment:

Pages 1050-1051, Section 3.14 Flight crew CVR autopilot announcements
This section states, in part:
The investigation could not determine a higher possibility to any of the above conditions based on the given data.

As previously provided for Section 2.5.14, Flight crew CVR autopilot announcements, the meaning of the flight crew's statements regarding the autopilot during this period are unambiguous. The captain's "autopilot" statements are consistent with requests for autopilot engagement. The first officer's statement, "Autopilot in command" is consistent with a rote response following a press of the command button. The first officer's statement, "No autopilot commander" was an attempt to communicate to the captain that the attempt to engage the autopilot was unsuccessful.

## U.S. Comment:

Pages 1051, Section 3.15 Rapid left roll towards wings level

Page 38 of 40

This section states, in part:

From the above, Captain Upset Recovery Attempt seems a higher possibility
This conclusion is unsupported. There is insufficient evidence to conclude which pilot made the recovery attempt.

## U.S. Comment:

Page 1051, Section 3.16 Impact with water

This section states, in part:
Although an attempt to correctly recover was initiated, the gravity of the upset condition with regards to attitude, altitude and speed made this attempt insufficient to achieve a successful recovery.

This section should clearly state that although the airplane remained responsive and controllable through out the entire flight, the overbank recovery attempt was begun too late to prevent impact with the ocean.
p. 1052, Findings, 3.1 Possible Causes

The draft final report provides the following as possible causes:

- Trim/ Feel Unit Fault (Aileron Trim Runaway)
- Temporarily, Spoiler wing cable jam (Spoiler offset of the neutral position)
- Temporarily, F/0 wheel jam (spoilers offset of the neutral position)
- Autopilot Actuator Hardover Fault
- A distraction developing to Spatial Disorientation (SD) until the time the F/0 announced "A/C turning right" with acknowledgement of the captain.

As stated in the U.S. team's cover letter to these comments, the only scenario that satisfies the logic and methodologies adopted by the investigative team is the one involving spatial disorientation. The remaining possible causes are not consistent with and would not lead to the sequence of events identified by the investigation.

Because the draft final report does not provide evidence or justification to conclude that the first four possible causes listed above may have occurred, these "possible causes" should be removed.

## U.S. Comment:

Page 1052, Findings
The draft final report properly notes that the path of the airplane was consistent with the recorded motion of the control surfaces. This should be added as a finding in this section.
U.S. Comment:
p. 1053, Conclusion

Page 39 of 40

The evidence and the analysis methodology agreed to and adopted by the full investigative team supports only a conclusion of spatial disorientation by the captain. The first officer's failure to assume timely control of the airplane should also be identified.
U.S. Comment:
p. 1054, Recommendations

Justification for recommendations 1 through 4 is unclear.
Regarding recommendation 3, it should be noted that there was no evidence the crew misunderstood the engagement status.

Regarding recommendation 4, it should be noted that the U.S. Federal Aviation Administration initiated an independent re-examination of the B-737 autopilot system early in the investigation. The FAA's review concluded that no safety action was required on the B-737 autopilot/flight director or attitude display systems. The results of this review were provided to the MCA on 13 December 2004.

Regarding recommendations 6 and 7, Industry developed "Airplane Upset Recovery Training" is currently available. These recommendations should be addressed to either operators for incorporation in training programs or to the CAA for regulatory action.

Regarding recommendation 8, it should be noted that spatial disorientation is a welldocumented phenomenon. It would be more appropriate to recommend awareness training for crews. This recommendation should be addressed to a specific organization.

Regarding recommendation 9, it should be noted that the CRM failings in this accident included a lack of assertiveness on the part of the first officer. This aspect should be better addressed in both operating procedures and CRM training. This recommendation should be addressed to either operators for incorporation in training programs or to the CAA for regulatory action.

Le Bourget, 2 January 2006

## Captain Shaker Kelada

Commission of Inquiry into accident at Sharm el-Sheikh Ministry of Civil Aviation
Airport Road P.O. Box 52
Heliolpolis, Cairo
Egypt
$\mathrm{N}^{\circ} \quad 000001$ /BEA/D
Subject: Draft Final Report - Comments
Your Ref: Flash airlines flight 604, 3 January 2004
Attachment :-

## Dear Captain Kelada,

Thank you for having associated the BEA (Bureau d'Enquêtes et d'Analyses pour la sécurité de l'Aviation Civile) with the investigation into the accident to the Boeing 737-300, registered SU-ZCF, and for the opportunity to make comments on the Draft Final Report. I would also like to reiterate our great appreciation for the spirit of cooperation that has permeated this investigation and for your consideration for the suffering of the families of the victims of the disaster.

It is in this same spirit, and with the interests of civil aviation safety in mind, that we hereby present you with the following observations. I hope that they will appear to you to improve the overall comprehension of the accident and that you will accept that they be included into your report. If this is not the case, I would be obliged if you would append this letter to the report, in accordance with the provisions of Annex 13.

## Part 1 (Factual Information)

The factual part of the report contains a certain number of errors and omissions that were identified in the course of the investigation. The BEA draws your attention to these points, and in particular that:

- There are erroneous values in the parameters in section 1.1 (History of Flight);
- Details of Flash Airlines pilots' flying activity were supplied during the investigation. They should be appended to the report. These details modify the information included on page 48-1;

Aéroport du Bourget
Bâtiment 153
93352 Le Bourget Cedex France
Tèl. : +33 149927200 Fax: +33149927203

- The CVR transcript does not take into account the additional information brought to light after further listening last August;
- The reports on the simulations undertaken in Seattle in October 2004 are not appended to the report;
- On several occasions, information supplied by the manufacturer is replaced by a note relating to proprietary information. It appears that the manufacturer does not, however, consider its explanations to be confidential. Consequently, the technical data that had previously been reserved should be included in the report.

## Part 2 (Analysis)

- On the basis of the analysis, the report accepts four possible technical failures. It should be noted that the extensive group work made it possible to eliminate the numerous cases examined, with the exception of two (Aileron trim runaway, Autopilot actuator hardover). Concerning these two hypotheses that were not eliminated, simulations undertaken showed that the crew would still have been able to control the airplane's track.
- An additional hypothesis implicating the rudder, which was never discussed during the group work, appears in the analysis. Examination of the factual elements supplied confirms that this hypothesis is not relevant in the context of the accident.
- The operational aspects, including those possibly related to the technical points raised, are not developed. It is, however, internationally recognised that examination of these elements is important and unavoidable in an aircraft accident report. It is necessary to examine why the crew, when confronted with an abnormal and unusual situation, did not seem to have either analyzed this situation or to have mobilized all of its available resources to deal with it. The CVR readout shows an absence of appropriate dialogue aimed at identifying a possible problem or proposing a solution to it.
- Cockpit Resource Management (CRM) training was not mandatory in Egypt at the time of the accident. The operator, in contradiction with the specific part in its Operations Manual and with the response given following the audit performed in January 2003 by the ECAA, had not set up such a training programme. It should also be noted that some other remarks made in the course of the audit were not in effect taken into account (notably in relation to recruitment of additional pilots and to follow-up on daily maintenance).
- In the analysis, it is necessary to examine the knowledge that the Captain possessed to enable him to identify and manage the crisis situation encountered during this flight, which implies studying the successive training programmes that he had followed. His activity for several years showed no evidence of any structured training in this area, nor more generally for the role of Captain. Thus, it seems that his initial conversion on ATR 42, along with the validation by equivalence of his Captain's license, corresponded neither to generally accepted qualification standards nor to Egyptian regulations. On the technical level, his type rating had been carried out on 737-500 and not on 737-300, without any training on the specificities of the fleet's airplane's (variant training) being included in the operator's documentation.
- Study of the «Human Factors », which is included in section 2.6, is based on documents supplied during the first meeting of the sub-group (August 2004).

Further work, undertaken with the assistance of American and French specialists for a second meeting of the sub-group (August 2005), is appended to the section but not developed. This work brought to light evidence of two probable phenomena, spatial disorientation and fatigue. Examination of these phenomena should be detailed and structured because of their importance both for an understanding of what did, or did not, happen during the flight as well as for safety in air transport. In fact, these physiological phenomena are of a type that may affect any pilot, whatever his or her experience, skills or state of health might be.

- In relation to fatigue in particular, it appears, according to documents supplied by the ECAA (regulations and crew service schedules) that the operator's management of the crew's periods of activity was not in accordance with the national regulations.

## Part 3 (Conclusions)

Bearing in mind the preceding, the BEA proposes the following modifications to the Findings and Conclusion.

- Section 3.1 (Possible causes): eliminate the two causes that were proved not to have contributed to the accident (bullets two and three).
- Section 3.2 (Possible contributing factors): add four factors
- Resources mobilised by the crew were not appropriate to the emergency situation encountered.
- Neither pilot had followed Cockpit Resource Management (CRM) training courses, noting that such training was not mandatory in Egypt at the time of the accident.
- The Captain had not followed a structured training programme for the role of Captain of a civil transport airplane.
- Taking into account his activity in the previous days, the Captain was very probably suffering from sleep deficit.
- Section 3.3 (Additional findings): add one factor
- At the time of the accident, the operator had not yet implemented various measures decided on following an audit carried out in January 2003.
- Concluding section: add, to the end of the last sentence of the first section, «while noting that the airplane remained controllable throughout the flight».

The BEA remains at your disposal for any further information that you may wish to obtain.

Yours sincerely.

## Le directeur du BEA

P.L. ARSLANIAN

## MCA Response:

Part 1 (Factual Information) adopted
Part 2 (Analysis): Hypothesis implicating the rudder adopted
$5^{\text {th }}$ January 2006

Dear Captain Shaker

## Comments of Flash Airlines upon draft final report into the loss of Flash Airlines Flight 604

Please find attached our comments upon the draft final report into the loss of Flash Airlines Flight 604 on 3 January 2004. We should be grateful if you and your Accident Investigation Team would consider our comments forthwith and let us know whether, in the light of these comments, you are prepared to amend the draft final report to reflect them. In the event that any of the attached comments are not reflected in amendments to the draft final report, we should be grateful if you would append a copy of the relevant comments to the final report.

[^56]177 ب ش الحعجاز - مصرالجدليدة - القاهرة - مصر

Comments of Flash Airlines upon the Draft Final Report into the loss of Flash Airlines Flight 604

Flash Airlines welcomes the opportunity to comment upon the draft Final Report of the Accident Investigation into the loss of Flash Airlines Flight 604 on 3 January 2004. Our comments are set out below. It should be noted that these comments reflect our analysis of the draft report within the limited time ( 60 days) and with the resources available to us following release of the draft to interested parties. They do not therefore necessarily represent Flash's final view on every issue and Flash's position is reserved generally in that regard.

## Spatial Disorientation

1. Flash does not accept the existence of any spatial disorientation ("SD") on the part of the flight crew, or that it is appropriate for the report to make any finding to that effect, in the absence of unequivocal and positive indicators of its presence. It follows from the analysis in 4-6 below that some other explanation must in any event be sought for the behaviour of the aircraft after the limited window referred to in those paragraphs and during the most critical phase of the flight. That being the case, it is inappropriate and unnecessary to speculate as to the existence of SD during any earlier phase of the flight, unless there is clear evidence of its existence.
2. The report's analysis of the possible existence of SD on the part of the Captain is, in any event, confusing. In particular, it is frequently unclear what sections of the report concerning this issue represent the views of the investigation team itself and what represent submissions made to it by others.
3. The key part of any such analysis must be to test the possible existence of SD at various stages of the flight against the CVR transcript evidence of the recorded remarks of the Captain and the information he was being given by the First Officer. The investigation team's views on, and the conclusions they draw (and why) from, each stage of this process should be clearly set out.
4. If one carries out the exercise referred to in 3 above, this supports the view that, even if there was any SD present on the part of the Captain at any stage of the flight, it had ended before the aircraft's roll to the right resulted in an overbank and long before the point at which, if the aircraft had been performing normally, the manoeuvre ceased to be easily recoverable by the flight crew. In particular, at 02:44:31 the First Officer stated "Aircraft is turning right". At 02:44:37 the Captain responded to this by saying "How turning right?" and at 02:44:41 (when the aircraft's bank angle was approximately $40^{\circ}$ ) "OK come out". At that time the ailerons are returned to beyond neutral, the high right roll rate stops and a momentary left roll rate occurs (quoting from the Factual Report). This demonstrates that, by this time at the latest, the Captain had assimilated the information he had been given by the First Officer and reacted correctly to it. At this stage, therefore, there can be no question that the Captain appreciated the aircraft's rolling movement and furthermore knew his right from his left in terms of inputs to the flight controls. Any SD on his part was, on the available evidence, over by this time.
5. The draft report appears to regard the movement of the ailerons recorded at 92393 (02:43:39) as the beginning of a right roll manoeuvre that continued until the aircraft recovery attempt began (see 2-5-9, page 4). This is incorrect. This was in fact the start of the aircraft rolling out onto the $140^{\circ} \mathrm{M}$ heading, where it then remained for approximately 9 seconds. This appears to have been a deliberate (and accurately flown) manoeuvre on the part of the Captain. There is no evidence of SD at this point. The critical roll to the right only commenced with the aileron movement seen at $92420(02: 44: 06)$ or 92421 ( $02: 44: 07$ ), some 4 or 5 seconds after disengagement of the autopilot.
6. The conclusion to be drawn from 4 and 5 above is that, even if there was any SD on the part of the Captain, it was relatively short lived and in any event ended before the aircraft's attitude became critical. In these circumstances, it is inappropriate for the Report to include SD as a possible cause of the accident (see "FINDINGS" at 3.1). At most (and subject to the comments made in 1 above), SD should be included as a possible contributing factor only.
7. Any analysis of the issue of SD should also consider what event might have triggered it (if it existed at all) and whether a failure or malfunction of any of the aircraft's systems are likely to be implicated in that.

## Autopilot disengagement

8. The potential significance of the autopilot disengagement has been obscured within the weight of detail contained within the draft report. This event occurs (at FDR frame 92416 or $02: 44: 02$ ) only 4 or 5 seconds before the aircraft commences the critical roll to the right. Is this just a coincidence? It is important to bear in mind that Boeing's/Honeywell's analysis of the possible reasons for the disengagement is entirely predicated on the assumption that the unit was in this regard performing as designed: ie that it would only have automatically disengaged for a reason anticipated in its design. (Indeed this assumption effectively underlies all of the aircraft system fault tree analyses included within the draft report.) An alternative approach is to treat the disengagement as an indicator of a possible problem with the aircraft's systems (and potentially one still undiagnosed). If that is the case, then one cannot rule out the possibility that the autopilot disconnected for a reason not yet analysed by Boeing/Honeywell. It also invests the closeness in timing between this event and the start of the right roll with potentially far more significance than presently appears from the draft report.
9. Even on the basis of Boeing's/Honeywell's own analysis, another reason should be added at 3.10 of the Conclusions as a possible reason for the autopilot disengagement: namely failure of the unit to synchronise and pressurise following engagement (see section 2-5-10, page 5 , of the draft report).

## Flight Director commands to the flight crew

10. The draft report rules out the possibility of erroneous Flight Director ("FD") commands to the flight crew, apparently on the basis of a Honeywell presentation to the effect that it is not possible to have valid FDR data with erroneous commands (see
for instance $2-5-11$, page 4 , footnote 1 ). However, the implicit assumption that all FCC FDR data is valid appears to be incorrect.
11. In particular, the FDR records show anomalous readings for the SEL COURSE 1 and SEL HEADING FCC L settings interspersed between what appear to be true readings. On the SEL COURSE 1 parameter, the FDR records show readings of 306.035 (assumed to be a correct reading as a course setting of 306 would coincide with the VOR radial to be flown from Sharm el-Sheikh) interspersed with readings of 359.912. Similarly on the SEL HEADING FCC L parameter, the FDR records show readings of 219.814 (the runway heading) and later 106.875 (again assumed to be valid readings) interspersed again with readings of 359.912 .
12. Boeing have described one of the anomalous SEL HEADING FCC L readings as "apparent data drop out" (see the comments on the graph at paragraph 1.16.1.2, page 163-1 of the draft report) and seemingly ignored both the other anomalous SEL HEADING FCC L readings and the anomalous SEL COURSE 1 readings. However, "data drop out" is a very unlikely explanation, given that the anomaly has affected only these parameters. It should be noted that, on a 12 digit binary readout for the range between $0^{\circ}$ and $360^{\circ}, 359.912$ corresponds to " 111111111111 ". These anomalous readings are positive evidence of a fault, which is unlikely to have been in the FDR. It is more probable that there was a fault in either the left FCC or in the MCP (Mode Control Panel). It is difficult in these circumstances to understand how the report can rule out the possibility that the FD was issuing erroneous roll commands to the flight crew. An erroneous roll command might well explain the commencement of the roll to the right following autopilot disengagement. Further, even if there was some SD present on the part of the Captain during the early part of that manoeuvre (in which regard see 1-6 above), it might help to explain what triggered this, particularly if the Captain was also receiving confusing displays on his EHSI (Electronic Horizontal Situation Indicator) due to a similar problem with Course Select. The report should analyse this whole issue.

## Possible rudder defect

13. There is no real analysis within the draft report of the potential role played by a rudder defect in explaining the accident and this issue deserves more attention in the final report. The draft report expressly does not rule this out as a possible factor. That being the case, and bearing in mind the part played by the B737 rudder in previous similar accidents, it is difficult to understand why a rudder defect is not listed within the possible causes at paragraph 3.1 of the Findings.

## Master Caution

14. The significance of the Master Caution being triggered twice during the flight (the first during taxi, the second towards the end of the flight) deserves more attention and analysis. The first occurred during the pre-flight rudder control check. Is this just a coincidence? The second should be analysed as possible evidence of a systems failure on the aircraft.
15. The draft report analyses at section 2-5-13, paragraph 6.2.2.3.1, a possible autopilot actuator fault, which it concludes shows close consistency with the event. The report states that this condition requires 3 concurrent faults, one of which could have been latent generally and a second of which could have been latent from any time after the last use of the autopilot on a previous flight. It fails however to emphasise sufficiently that they also could all be triggered by an electrical short within the electrical socket on the autopilot actuator and could therefore have a single, common, cause.

## Aileron Trim Runaway

16. The draft report also analyses an aileron trim runaway and concludes that it cannot be ruled out as a possible condition and shows close consistency with the event. This systems failure required only two concurrent faults, one of which could have been latent. One feature of such a failure that the report does not draw adequate attention to is the fact that a trim runaway would take some time to produce full aileron deflection and would therefore produce a roll which gradually deteriorated into an overbank (the same situation as occurred in this case).

## Recorded aileron movements

17. The report notes that, even during the attempted recovery phase at the end of the flight, aileron action is recorded in both directions. The potential importance of this finding is not explored in the draft report. Yet it would seem to be evidence of the pilot in command fighting some countervailing force during this period. Similar indications can be found earlier at FDR frame 92432 (02:44:18), when the Captain said "See what the aircraft did" (aileron movement for one or two seconds asking for left roll, presumably in response to the aircraft movement which provoked the Captain's comment, followed by aileron movements commanding right wing down), and at FDR frame 92453 (02:44:39), just before the Captain said "OK come out" (large aileron movement asking for left wing down, producing the momentary left roll noted in the Factual Report, followed by more right wing down aileron movements). These readings suggest deliberate left wing down inputs by the Captain (coinciding with consistent statements on the CVR record), followed by a resumption of right roll commands as soon as he relaxes on the control wheel. This is very significant evidence of the possible existence of some form of systems failure or malfunction.

## No reliable control wheel FDR data

18. It seems remarkable that the only parameter on which there is no reliable recorded data on the FDR is the control wheel position. Is it possible that the condition which led to the control wheel sensors producing anomalous results also affected the functioning of the control wheels themselves?

## Draft Findings

19. At paragraph 3.2 of the Findings, the first two items (tech log copies left on board; write up of defects) should be removed from the possible contributory factors.

Whatever the position may have been regarding these matters (as to which Flash expressly reserves its position), there is no evidence that these matters had anything whatsoever to do with the accident.
20. Even leaving to one side the point made in 1 above, we do not consider it appropriate for the remaining two items of paragraph 3.2 to be included as possible contributing factors. If they are to appear anywhere, they should appear elsewhere within the report since (as currently drafted) they are simply part of the report's analysis.

## General

21. It is inappropriate for the final report to contain blank pages due to Boeing's refusal to release proprietary data. If the information which would have been included there is relevant to the report's findings, it should be set out or summarised and interested parties should be given a further opportunity to comment before a final report containing such data is released.
22. Both paragraphs 1.5.1.6 and 1.5.2.6 of the draft report state that "no official head of operation in Flash Airlines" was (apparently) available for interview during the investigation. On a point of information, the company's Operations Manager on the date of the accident was Ihab El Sonbaty, who was one of the off duty crew members killed in the accident.

In the event that any of the above comments are not reflected in amendments to the draft Final Report, we should be grateful if you would append a copy of the relevant comments to the Final Report.

## MCA Response:

Spatial Disorientation comment adopted

Submission by Egyptain Civil Aviation Authority to the draft report of the Flash Airlines accident investigation i
Dear Captain Kelada
The ECAA being a party to this investigation thank the investigation committee for their effort and the chance to give our comments on the draft report.
Having participated in the different groups of the investigation we are comfortable with the findings that have been offered in general, nevertheless we would like to make one comment that has come out of the Crew Behavior Subcommittee.
The ECAA studies are in agreement with the draft report that the Captain was temporary distracted and may have developed to temporary spatial disorientation having said that it is apparent this state is a consequent result of a previous action.
Based on these facts the phase of distraction and spatial disorientation was a reaction to some previous happening and therefore this finding could have only contributed to the accident.
The ECAA requests the finding of the crew behavior's distractions and possible spatial disorientation be considered a possible contribution factor.
We would appreciate the above to either be amended or appended in the final report

## Best Regards

Pilot / Samir Abdel-Maboud Abdel-Aziz

Head of,
Egyptian Civil Aviation Authority
